August 2017

Acknowledgments

The Tucannon River Spring Chinook Salmon Hatchery Evaluation Program is the result of efforts by many individuals within the Washington Department of Fish and Wildlife (WDFW) and from other agencies.

We would like to express our sincere gratitude to Ace Trump, Lyons Ferry Hatchery Complex Manager and Hatchery Specialists Steve Jones, Dan Pounds, Scott Breslin, Doug Maxey, and Dick Rogers for their cooperation with hatchery sampling, providing information regarding hatchery operations and hatchery records, and their input on evaluation and research activities. We also thank all additional hatchery personnel who provide the day-to-day care of the spring Chinook and for their assistance with hatchery spawning, sampling, and record keeping.

We thank Lynn Anderson and the Coded-Wire Tag Lab staff for their assistance in coded-wire tag verification. We also thank Lance Campbell and Andrew Claiborne for providing scale ages, and Meghan Baker and Elizabeth Bamberger for information on fish health during the year. Special thanks go to David Bramwell for help formatting this report.

We thank the staff of the Snake River Lab; in particular Joe Bumgarner, Jerry Dedloff, Debbie Milks, Todd Miller, Afton Oakerman, and seasonal workers Debbie Conwell, Brigido Garcia, Sarah Golden, Valerie Miranda, Bridget Sloat, Joshua Stedman, Steven Sweet, and Sarah Windsor who helped collect the information presented in this report. We also thank Ethan Crawford and the staff of the Asotin Creek Field Office for assisting us with spawning ground surveys on Asotin Creek.

We thank Joe Bumgarner, Alf Haukenes, Rod Engle, and Erik Neatherlin for reviewing the draft report.

The United States Fish and Wildlife Service through the Lower Snake River Compensation Plan Office funded the supplementation program. A grant through the Bonneville Power Administration provided funding for a portion of the hatchery program PIT tags.

Abstract

Lyons Ferry Hatchery (LFH) and Tucannon Fish Hatchery (TFH) were built/modified under the Lower Snake River Fish and Wildlife Compensation Plan. One objective of the Plan is to compensate for the estimated annual loss of 5,760 (1,152 above the project area and 4,608 below the project area for harvest) Tucannon River spring Chinook caused by hydroelectric projects on the Snake River. With co-manager agreement, the conventional supplementation production goal was increased in 2006 from 132,000 to 225,000 fish for release as yearlings. This report summarizes activities of the Washington Department of Fish and Wildlife Lower Snake River Hatchery Evaluation Program for Tucannon River spring Chinook for the period May 2016 to April 2017.

A total of 595 salmon were captured in the TFH trap in 2016 (116 natural adults, 11 natural jacks, 299 hatchery adults, and 169 hatchery jacks). Of these, 126 (55 natural, 71 hatchery) were collected and hauled to LFH for broodstock, 330 were held at LFH for adult outplanting, and the remaining fish were passed upstream. During 2016, three (2.4%) salmon collected for broodstock died prior to spawning.

Spawning of supplementation fish occurred once a week between 30 August and 20 September, with peak eggtake occurring on 6 September. A total of 245,174 eggs were collected from 31 natural and 41 hatchery-origin female Chinook. Egg mortality to eye-up was 4.5% (10,999 eggs) which left 234,175 live eggs. An additional 1.7% (4,069) loss of sac-fry left 230,106 BY 2016 fish for production.

Due to the relatively low run size in 2016 and the recent high pre-spawn mortality rates for Tucannon River spring Chinook, fish managers decided to hold a portion of the returning adults at LFH and then returning those fish to the upper stream reaches near the beginning of spawning. A total of 296 fish were returned to the river in small groups (~15 pairs/group) and released between Curl Lake (rkm 65.6) and Lady Bug Flat Campground (rkm 77.8) at nine different locations on 22 August and 23 August. Four pre-spawn mortalities of outplanted fish were recovered.

Evaluations personnel conducted pre-spawn mortality surveys in the Tucannon River between 23 June and 19 August during 2016, after which regular weekly spawning ground surveys commenced. These surveys covered from Camp Wooten (rkm 68) to Bridge 12 (rkm 47). Weekly spawning ground surveys were conducted from 26 August and were completed by 30 September 2016. A total of 154 redds and 113 carcasses (39 natural, 74 hatchery) were found. Based on redd counts, carcasses recovered, and broodstock collection, the estimated return to the

river for 2016 was 752 spring Chinook (215 natural adults, 8 natural jacks and 397 hatchery-origin adults, 132 hatchery jacks).

Volitional release of the 2015 BY smolts began on 4 April and continued until 21 April, 2017 when the remaining fish were forced out. An estimated 199,686 BY15 smolts were released.

Evaluation staff operated a downstream migrant trap to provide juvenile outmigration estimates. During the 2015/2016 emigration, we estimated that 6,604 (5,674-7,696 95% C.I.) natural spring Chinook (BY 2014) smolts emigrated from the Tucannon River.

Smolt-to-adult return rates (SAR) for natural origin salmon were almost eight times higher on average (based on geometric means) than hatchery origin salmon. However, hatchery salmon survive almost three times greater than natural salmon from parent to adult progeny.

Preliminary data does not show a significant benefit in either survival or homing back to the Tucannon River by rearing fish at TFH instead of LFH. Unless future data shows a different result, we will continue to use LFH for holding, spawning, and incubation and early life rearing of Tucannon River spring Chinook.

Introduction

Program Objectives

Legislation under the Water Resources Act of 1976 authorized the establishment of the Lower Snake River Compensation Plan (LSRCP) to help mitigate for the losses of salmon and steelhead runs due to construction and operation of the Snake River dams and authorized hatchery construction and production in Washington, Idaho, and Oregon as a mitigation tool (USACE 1975). In Washington, Lyons Ferry Hatchery (LFH) was constructed and Tucannon Fish Hatchery (TFH) was modified. Under the mitigation negotiations, local fish and wildlife agencies determined through a series of conversion rates of McNary Dam counts that 2,400 spring Chinook (2% of passage at McNary Dam) annually escaped into the Tucannon River. The agencies also estimated a 48% cumulative loss rate to juvenile downstream migrants passing through the four lower Snake River dams. As such, 1,152¹ lost adult Tucannon River origin spring Chinook needed to be compensated for above the project area, with the expectation that the other 1,248 (52%) would continue to come from natural production. An additional 4,608 needed to be compensated for to provide harvest below the project area for a total mitigation goal of 5,760 Tucannon River spring Chinook. The agencies also determined through other survival studies at the time that a smolt-to-adult survival rate (SAR) to the project area of 0.87% was a reasonable expectation for spring and summer Chinook salmon. Based on an assumed 0.87% above project area SAR and the 1,152 above project area mitigation goal it was determined that 132,000 smolts needed to be released annually. In 1984, Washington Department of Fish and Wildlife² (WDFW) began to evaluate the success of these two hatcheries in meeting the mitigation goal, and identifying factors that would improve performance of the hatchery fish.

In an attempt to increase adult returns and come closer to achieving the LSRCP mitigation goal, the co-managers agreed to increase the conventional supplementation program goal to 225,000 yearling smolts annually beginning with the 2006 brood year. Size at release was increased to 38 g fish (12 fpp) beginning with the 2011 brood year. This report summarizes work performed by the WDFW Tucannon Spring Chinook Evaluation Program from May 2016 through April 2017.

¹The project area escapement is 1,152. It was also assumed that four times that number (4,608 fish) would be harvested below the project area. Here "project area" is defined as above Ice Harbor Dam.

² Formerly Washington Department of Fisheries.

ESA Permits

The Tucannon River spring Chinook population was originally listed as "endangered" under the Endangered Species Act (ESA) on April 22, 1992 (FR 57 No. 78: 14653). The listing status was changed to "threatened" in 1995 (April 17, 1995; FR 60 No. 73: 19342). The listing was reviewed again in 1999 (FR 64 (57): 14517-14528) with the population remaining listed as "threatened" as part of the Snake River Spring/Summer Chinook Salmon evolutionary significant unit (ESU). The WDFW was originally issued a Section 10 Permit (#848 – broodstock collection and monitoring) which expired in March 1998. Permits #1126 and #1129 were issued in 1998 to allow continued take for this program, but those permits have since expired. A Hatchery and Genetic Management Plan (HGMP) was originally submitted as the application for a new Section 4 (d) Permit for this program in 2005. An updated HGMP requesting ESA Section 10 permit coverage was submitted in 2011, and was approved in 2016 (Permit #18024). This annual report summarizes all work performed by WDFW's LSRCP Tucannon Spring Chinook Salmon Evaluation Program during 2016. Numbers of direct and indirect takes of listed Snake River spring Chinook (Tucannon River stock) for the 2016 calendar year are presented in Appendix A (Tables 1-2).

Facility Descriptions

Lyons Ferry Hatchery is located on the Snake River (rkm 90) at its confluence with the Palouse River and has eight deep wells that produce nearly constant 11° C water (Figure 1). It is used for adult broodstock holding and spawning, and early life incubation and rearing. All juvenile fish are marked and returned to TFH in late September/October for final rearing and acclimation.

Tucannon Fish Hatchery, located at rkm 59 on the Tucannon River, has an adult collection trap on site (Figure 1). Adults returning to TFH are transported to LFH and held until spawning. Juveniles are reared at TFH through the winter until release in the spring on a combination of well, spring, and river water. River water is the primary water source, which allows for a more natural winter temperature profile. In February/March, the fish are transported to Curl Lake Acclimation Pond (AP) located at rkm 66, a 0.85 hectare natural bottom lake with a mean depth of 2.7 m, and volitionally released during April.

Tucannon River Watershed Characteristics

The Tucannon River empties into the Snake River between Little Goose and Lower Monumental Dams approximately 622 rkm from the mouth of the Columbia River (Figure 1). Stream elevation rises from 150 m at the mouth to 1,640 m at the headwaters (Bugert et al. 1990). Total watershed area is approximately 1,295 km². Local habitat problems related to logging, road

building, recreation, and agriculture/livestock grazing have limited the production potential of spring Chinook in the Tucannon River. Land use in the Tucannon watershed is approximately 36% grazed rangeland, 33% dry cropland, 23% forest, 6% WDFW, and 2% other use (Tucannon Subbasin Summary 2001). Five unique strata have been distinguished by predominant land use, habitat, and landmarks (Figure 1; Table 1) and are referenced throughout this report.

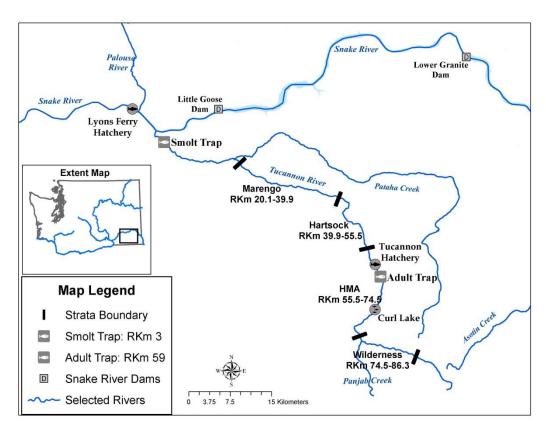

Figure 1. Location of the Tucannon River, and Lyons Ferry and Tucannon Hatcheries within the Snake River basin.

Table 1. Description of five strata within the Tucannon River.

Strata	Land Ownership/Usage	Spring Chinook Habitat ^a	River Kilometer ^b
Lower	Private/Agriculture & Ranching	Not-Usable (temperature limited)	0.0-20.1
Marengo	Private/Agriculture & Ranching	Marginal (temperature limited)	20.1-39.9
Hartsock	Private/Agriculture & Ranching	Fair to Good	39.9-55.5
HMA	State & Federal/Recreational	Good to Excellent	55.5-74.5
Wilderness	Federal/Recreational	Excellent	74.5-86.3

^a Strata were based on water temperature, habitat, and landowner use.

^b Rkm descriptions: 0.0–mouth at the Snake River; 20.1-Territorial Rd.; 39.9–Marengo Br.; 55.5-HMA Boundary Fence; 74.5-Panjab Br.; 86.3-Rucherts Camp.

Adult Salmon Evaluation

Broodstock Trapping

The allowed collection goal for broodstock is 170 adult salmon, depending upon size and fecundity, collected from throughout the duration of the run to meet the smolt production/release goal of 225,000. The proportion of natural origin fish incorporated into the broodstock is based on the estimated run size and the Tucannon Spring Chinook Salmon Hatchery and Genetic Management Plan sliding scale. Additional jack salmon may be collected up to their proportion of the run with an upper limit of 10% of the broodstock. Returning Tucannon hatchery salmon were identified by coded-wire tag (CWT) in the snout. All adipose clipped fish captured at the trap are killed outright as strays.

The TFH adult trap began operation in February (for steelhead) with the first spring Chinook captured on 10 May. State and Tribal Fisheries Managers decided to collect all Tucannon River returns that would not be used for broodstock and hold them at LFH for outplanting back into the river closer to the commencement of spawning (See Adult Outplanting Section). These measures were taken due to the high pre-spawn mortality rates observed in recent years. The majority of hatchery jacks were killed outright at the trap for fish management purposes. The trap was operated through September. A total of 595 fish entered the trap (116 natural adults, 11 natural jacks, 299 hatchery adults, and 169 hatchery jacks), and 55 natural (55 adults, 0 jacks) and 71 hatchery (71 adults, 0 jacks) spring Chinook were collected and hauled to LFH for broodstock (Table 2, Appendix B). Fish held for adult outplanting were given a right opercle punch and included 66 natural (57 adults, 9 jacks) and 264 hatchery origin fish (203 adults, 61 jacks). Fish not collected for transport to LFH were given a left opercle punch and passed upstream (25 total fish). Adults collected for broodstock were injected with tulathromycin (Draxxin³) at 2.5 mg/kg and oxytetracycline at 22 mg/kg, but fish held for adult outplants were not injected per WDFW Fish Health regulations. Broodstock and fish held for adult ouplanting were transported to LFH and received formalin drip treatments during holding at 167 ppm every other day at LFH to control fungus.

³ The use of trade names does not imply endorsement by the Washington Department of Fish and Wildlife.

Table 2. Numbers of spring Chinook salmon captured at the TFH trap, trap mortalities, strays or jacks killed outright, fish collected for broodstock, and passed upstream or held for adult outplanting for natural spawning from 1986-2016.

^a Fish identified as strays at the adult trap are killed outright. Some hatchery jacks were killed outright in 2016.

^b Two males (one natural, one hatchery) captured were transported back downstream to spawn in the river.

^c Three hatchery males that were captured were transported back downstream to spawn in the river.

^d Ninety-four natural origin fish were collected for broodstock, however eight natural origin females were returned to the river for natural spawning leaving a total of 86 natural origin fish collected for broodstock.

Broodstock Mortality

Three (2.4%) of the 126 salmon collected for broodstock died prior to spawning in 2016 (Table 3). One of the pre-spawn mortalities was a stray hatchery male (CWT 090719 – Umatilla River). Table 3 shows that pre-spawning mortality in 2016 was comparable to the mortality documented since broodstock holding at LFH began in 1992. Higher mortality was experienced when fish were held at TFH (1986-1991), likely due to higher water temperatures.

Table 3. Numbers of pre-spawning mortalities and percent of fish collected for broodstock at TFH and held at TFH (1985-1991) or LFH (1992-2016).

	`	Natural	•	,	Hatchery			
Year	Male	Female	Jack	% of collected	Male	Female	Jack	% of collected

Broodstock Spawning

Spawning at LFH was conducted once a week from 30 August to 20 September, with peak eggtake occurring on 6 September. During the spawning process, the eggs of two females were split in half and fertilized by two males following a 2 x 2 factorial spawning matrix approach. Factorial mating can have substantial advantages in increasing the genetically effective number of breeders (Busack and Knudsen 2007). The priority order of crosses were Natural x Hatchery, Natural x Natural, and Hatchery x Hatchery, depending upon availability of fish. Two hatchery males and two hatchery females were identified as Umatilla Hatchery strays during spawning based on reading their CWT and their gametes were destroyed and not used for production.

A total of 245,174 eggs were collected (Table 4). Eggs were initially disinfected and water hardened for one hour in an iodophor (buffered iodine) solution (100 ppm). The eggs were incubated in vertical tray incubators. Fungus on the incubating eggs was controlled with formalin applied every-other day at 1,667 ppm for 15 minutes. Mortality to eye-up was 4.5% which left 234,175 live eggs. An additional 1.7% (4,069) loss of sac-fry left 230,106 fish for production.

Table 4. Number of fish spawned or killed outright (K.O.), estimated egg collection, and egg mortality of natural and hatchery origin Tucannon River spring Chinook salmon at LFH in 2016. (Numbers in parentheses were live spawned).

^a Eleven were previously live spawned and sampled at the completion of spawning.

^b This female was green and killed outright.

Adult Outplanting

After discussions with the Tribal co-managers, it was decided to collect all returning fish not collected for broodstock or killed outright (strays, hatchery jacks) and hold them at LFH for adult outplanting back into the river during late August near the on-set of spawning. This decision was made due to the relatively low run size and the high pre-spawn mortality rate of adult spring Chinook salmon that has been documented in the Tucannon River in recent years (Gallinat and Ross 2014; Gallinat and Ross 2015; Snake River Lab 2015). Collected fish would be returned to the river between Beaver/Watson Bridge and Lady Bug Flat Campground (rkms 62-78).

A total of 330 fish (66 natural origin, 264 hatchery origin) were collected for adult outplanting. Held fish were treated with formalin to control fungus growth, but were not injected with antibiotics. Of the fish that were held, three natural origin and 26 hatchery origin fish died at LFH (8.8% pre-spawn mortalities). In addition, five hatchery origin fish were determined to be strays (AD clipped) and were killed outright. The remaining 296 fish were transported back to the river in small groups (~ 15 pairs/group) and released at or above Curl Lake (rkm 65.6) at nine different locations on 22 August and 23 August (Table 5). Fish captured in the adult trap after 21 August were given a left opercle punch (LOP) and released upstream. Stream surveys were conducted prior to and following adult outplanting and four pre-spawn mortalities of outplanted fish were recovered.

Table 5. The number of Tucannon River spring Chinook outplanted in the Tucannon River by release location during 2016.

-	Release					
Date	Location	Rkm	Females	Males	Jacks	Total
8/22/16	Lady Bug Flat Campground	77.8	15	8	6	29
8/22/16	Panjab Bridge	74.5	30	16	12	58
8/22/16	Private Lands Campsite	73.3	15	8	6	29
8/22/16	Campground above Cow Camp	73.1	15	8	6	29
8/22/16	Campground at Cow Camp Br.	72.9	15	10	2	27
8/23/16	Across from Camp Wooten	68.4	15	8	6	29
8/23/16	Camp Wooten Bridge	68.1	15	8	6	29
8/23/16	Curl Lake Intake	66.1	15	8	6	29
8/23/16	Behind Curl Lake	65.6	3	17	17	37
Totals			138	91	67	296

Only one outplanted hatchery jack (ROP) was recovered below the outplant area at rkm 59.4, suggesting that movement of outplanted fish from the release sites was negligible. Some redd superimposition was observed in the upper watershed suggesting available suitable spawning areas were saturated.

Natural Spawning

Pre-spawn mortality surveys were conducted from 23 June to 19 August during 2016, after which regular weekly spawning ground surveys commenced. Although fish were not passed above the trap prior to 21 August, pre-spawn mortality surveys were still conducted upstream of the trap in case fish were able to bypass the trap. The pre-spawning mortality surveys covered from Camp Wooten (rkm 68) to Bridge 12 (rkm 47). Only one unidentified origin female was recovered (rkm 58.6) during pre-spawn mortality surveys. Six other pre-spawn mortalities were recovered during regular spawning ground surveys. This included four fish (two hatchery origin, two natural origin) above the trap from the adult outplant group and two fish (hatchery origin) below the adult trap. Cause of death could not be determined for any of the recovered pre-spawn mortalities, but many had been partially to mostly consumed by predators/scavengers.

Weekly spawning ground surveys were conducted from 26 August and were completed by 30 September 2016. One hundred fifty-four redds were counted and a total of 39 natural and 74 hatchery origin carcasses were recovered (Table 6). Eighty-three redds (54% of total) and 76 carcasses (67% of total) were found above the adult trap. Adult outplanting during 2016 indicated that there was a low conversion rate of females to eventual redd (151 females outplanted or passed upstream and only 83 redds produced for a 55% conversion rate).

Table 6. Numbers and general locations of salmon redds and carcasses (includes pre-spawn mortalities) recovered on the Tucannon River spawning grounds, 2016 (the Tucannon Hatchery adult trap is located at rkm 59).

(Brines Rd.).

Historical Trends in Natural Spawning

Two general spawning trends were evident (Figure 2) from the program's inception in 1985 through 1999:

- 1) The proportion of the total number of redds occurring below the adult trap increased; and
- 2) The density of redds (redds/km) decreased in the Tucannon River.

In part, these two factors were a result of a greater emphasis on broodstock collection in an effort to reduce the risk of extinction. However, increases in the SAR rates beginning with the 1995 brood have subsequently resulted in increased spawning above the trap and higher redd densities (Figure 2; Table 7). Also, moving the release location from TFH (rkm 57.7) upstream to Curl Lake AP (rkm 65.6) in 1999 appears to have affected the spawning distribution, with higher numbers of fish and redds in the Wilderness and HMA strata compared to previous years (Table 7).

Note: – indicates the river was not surveyed in that section during that year.

^a Excludes redds found below the Marengo stratum.

^b Includes all redds counted during redd surveys.

^c The 1985 redd counts were revised to account for all redds during the spawning season (WDFW 2015).

Stream Nutrient Enrichment

The majority of hatchery broodstock carcasses have traditionally been buried on-site at LFH after spawning. However, declines in salmonid abundance during the last century have resulted in decreased deposition of marine-derived nutrients and pose a significant restraint in the recovery of threatened and endangered Pacific salmon (Nehlsen et al. 1991; Scheuerell et al. 2005). The importance of marine derived nutrients to salmon recovery efforts has prompted local volunteer groups and state, federal, and tribal agencies to add supplemental nutrients into freshwater habitats, especially in salmon depleted habitats (Kohler et al. 2012).

A total of 304 fall Chinook and 148 spring Chinook carcasses were available for stream nutrient enrichment in the Tucannon River during 2016. Virology testing did not show signs of disease so the "Protocols for the Nutrient Enrichment of the Tucannon River to Increase Production of Salmon and Steelhead" were followed and fall Chinook carcasses, due to their relative abundance, were used as a surrogate for spring Chinook carcasses. Department employees and volunteers from the Tri-State Steelheaders Regional Fisheries Enhancement Group distributed the carcasses between Panjab Bridge (rkm 74.5) and Bridge 11 (rkm 44.0) from 14-19 December, 2016 (Table 8). Carcasses were distributed based on 2016 redd locations and expected downstream movement of juveniles.

Genetic Sampling

During 2016, we collected 207 DNA samples (tissue samples) from hatchery broodstock and carcasses collected from the spawning grounds (85 natural origin, 109 hatchery supplementation, and 13 hatchery origin strays). These samples were sent to the WDFW genetics lab in Olympia, Washington for storage. Genotypes, allele frequencies, and tissue samples from previous sampling years are available from WDFW's Genetics Laboratory.

Age Composition, Length Comparisons, and Fecundity

We determine the age composition of each year's returning adults from scale samples of natural origin fish, and both scales and CWTs from hatchery-origin fish. This enables us to annually compare ages of natural and hatchery-reared fish, and to examine trends and variability in age structure. Due to the management decision in 2016 to kill hatchery jacks outright at the adult trap, the proportion of jacks sampled from the population were skewed higher than if samples were collected only from recovered carcasses. Therefore, we adjusted the proportion of hatchery jacks using a simple linear regression describing the relationship between the proportion of hatchery jacks trapped at the TFH adult trap and the expanded proportion of hatchery jacks based on the historical run size for the 2000-2015 run years ($r^2 = 74\%$; P < 0.01):

Proportion of Hatchery Jacks (expanded) = -6.718 + 0.912(Proportion of Hatch. Jacks Trapped)

Overall, hatchery origin fish return at a younger age than natural origin fish and have fewer age-5 fish in the population (Figure 3). This difference is likely due to larger size-at-release that can lead to higher proportions of early maturating fish (hatchery origin smolts are generally 25-30 mm greater in length than natural smolts). The age composition for natural origin fish that returned in 2016 had more age-5 fish compared to the historical age composition (Figure 3). While there are more older age fish in the natural component of the population, we have not seen significant change in the mean age (weighted) of males and females over 27 brood years (Figure 4). The age composition by brood year for natural and hatchery origin fish is found in Appendix C.

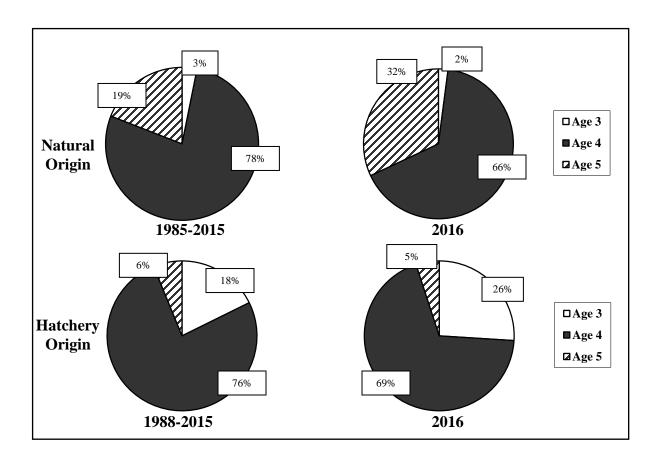

Figure 3. Historical (1985-2015), and 2016 age composition (run year) for spring Chinook in the Tucannon River.

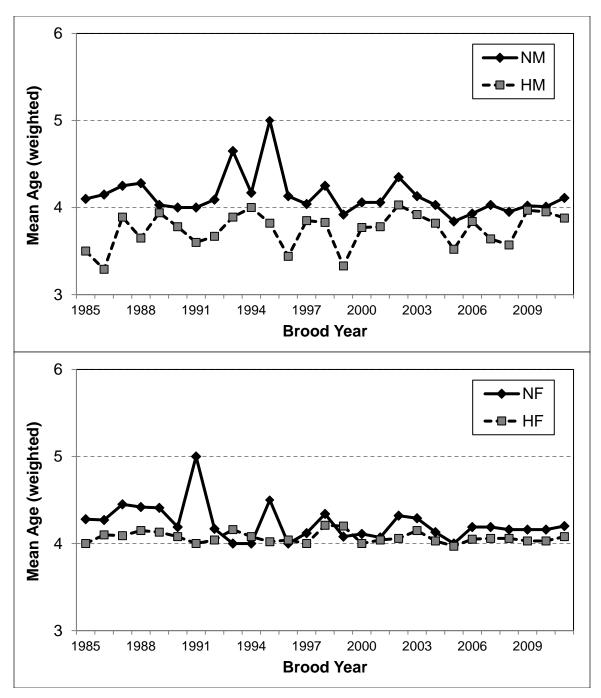

Figure 4. Weighted mean age of natural and hatchery origin males (NM, HM) and natural and hatchery origin females (NF, HF) for the 1985 to 2011 brood years for spring Chinook in the Tucannon River.

Another metric monitored on returning adult natural and hatchery origin fish is size at age, measured as the mean post-orbital to hypural-plate (POH) length. We examined size at age for returns using multiple comparison analysis from 1985-2016 and found a significant difference (P < 0.05) in mean POH length between age-4 natural and hatchery-origin female, and age-4 natural and hatchery-origin male spring Chinook salmon (Figure 5).

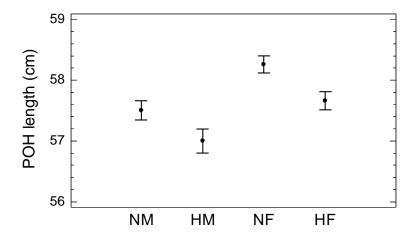

Figure 5. Mean post-orbital to hypural-plate (POH) length comparisons between age-4 natural and hatchery-origin males (NM and HM) and natural and hatchery-origin females (NF and HF) with 95% confidence intervals for the years 1985-2016.

To estimate fecundities (number of eggs/female) from the 2016 return year, dead eggs were counted for each female and a subsample of 100 live eyed-eggs was weighed. The total mass of live eggs was also weighed, and divided by the average weight per egg to yield total number of live eggs. This estimate was decreased by 4% to compensate for adherence of water on the eggs (WDFW Snake River Lab, unpublished data). Fecundities of natural and hatchery origin fish from the Tucannon River program have been documented since 1990 (Table 9). We performed an analysis of variance to determine if there were differences in mean fecundities of hatchery and natural origin fish. The significance level for all statistical tests was 0.05. Natural origin females were significantly more fecund than hatchery origin fish for both age-4 (P < 0.001) and age-5 fish (P < 0.001).

These data correspond with data collected by Gallinat and Chang (2013) that examined the effects of hatchery rearing on selected phenotypic traits of female Tucannon River spring Chinook salmon. They found that hatchery origin females had significantly lower fecundity than natural origin fish after correcting for body size. They also observed that the progeny of captive-

reared broodstock, released as smolts and recaptured as returning age-4 adults, had a size and fecundity distribution that was similar to the hatchery-origin adults, suggesting that the decrease in fecundity was related to hatchery rearing and not a genetically linked trait.

Table 9. Average number of eggs/female (n, SD) by age group of Tucannon River natural and hatchery origin broodstock, 1990-2016 (partial spawned females are excluded).

Arrival and Spawn Timing Trends

We monitor peak arrival and spawn timing to determine whether the hatchery program has caused a shift (Table 10). Peak arrival dates were based on the greatest number of fish trapped on a single day. Peak spawn in the hatchery was determined by the day when the most females were spawned. Peak spawning in the river was determined by the highest weekly redd count.

Peak arrival to the adult trap for natural origin fish was earlier than normal during 2016 but was within the historical range (Table 10). However, this earlier arrival may have been due to a smaller run size since the next highest number of natural origin fish at the adult trap was the same date (6 June) as the peak for hatchery origin fish (Table 10). Peak spawning date in the hatchery was close to the historical means and was 13 September for hatchery fish and 6 September for natural origin fish (Table 10). The duration of spawning in the hatchery was also within the historical mean. Spawning in the river peaked on 7 September. The duration of active spawning in the Tucannon River was within the range found from previous years.

Natural origin fish typically arrive earlier and at a slightly faster rate than hatchery origin fish (Figure 6). On average, about half of the total run of hatchery origin fish typically arrives at the adult trap by 12 June (Figure 6). After the end of June, the hatchery fish tend to arrive at the adult trap at a slightly faster rate than natural origin fish.

Table 10. Peak dates of arrival of natural and hatchery salmon to the TFH adult trap and peak (date) and duration (number of days) for spawning in the hatchery and river, 1986-2016.

^a Too few natural salmon were trapped in 1995 and 1999 to determine peak arrival.

^b Access restrictions during the Columbia Complex Forest Fire prohibited spawning ground surveys during the beginning of spawning.

^c Unspawned females determined to be in excess of eggtake goals were returned to the river for natural spawning which may have truncated duration of spawning in the hatchery.

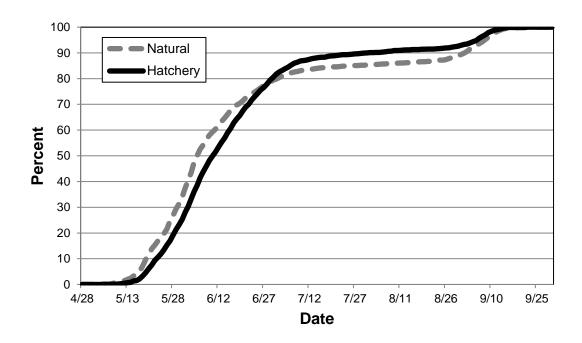

Figure 6. Cumulative run timing by date at the Tucannon Fish Hatchery adult trap on the Tucannon River for both natural and hatchery origin Tucannon River spring Chinook salmon, 1994-2016.

Total Run-Size

Not passing any fish above the adult trap until the end of August and the use of adult outplants (See Adult Outplanting Section) has confounded our calculations of fish below the adult trap. Hatchery staff passed six natural origin and 19 hatchery origin fish upstream of the trap (left opercle punch) for a total of 25 fish passed upstream. There were a total of 296 (63 natural origin, 233 hatchery origin) total adult outplants (right opercle punch). No fish without an opercle punch were recovered above the trap so we made the assumption that no fish were able to bypass the trap in 2016. No fish that passed over the trap or were outplanted upstream (left or right opercle punched carcasses) were recovered below the trap, so we assumed little to no fallback at the trap. We calculated the number of fish below the trap by using the fish/redd estimate (2.21 – from the spawning escapement calculation) and multiplied that by the number of redds below the trap (71) for a total of 157 fish below the trap.

The run-size estimate for 2016 was calculated by adding the estimated number of fish upstream of the TFH adult trap (321), the estimated fish below the weir (157), the number of pre-spawn mortalities and strays killed outright from fish held at LFH for adult outplanting (34), strays and hatchery jacks killed at the trap for management purposes (114), and the number of broodstock collected (126) (Table 11). Run-size for 2016 was estimated to be 752 fish (215 natural adults, 8

natural jacks, and 397 hatchery adults, 132 hatchery-origin jacks). Historical breakdowns are provided in Appendix D.

^a In 1994, 1995, 1998 and 1999, fish were not passed upstream, and in 1996 and 1997, high pre-spawning mortality occurred in fish passed above the trap, therefore; fish/redd ratio was based on the sex ratio of broodstock collected.

b From 1985-1989 the TFH trap was temporary, thereby underestimating total fish passed upstream of the trap. The 1985-1989 fish/redd ratios were calculated from the 1990-1993 average, excluding 1991 because of a large jack run.

^c This total includes stray fish that are killed at the trap and pre-spawn mortalities of fish held at LFH for adult outplanting. During 2016 jacks were killed outright at the adult trap and are included in this total.

d Effort in looking for pre-spawn mortalities has varied from year to year with more effort expended during years with poor conditions or large runs.

^e The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2016).

f The fish/redd ratio was not used to estimate the number of fish below the adult trap due to survival differences between outplanted fish and fish that were passed upstream.

Spawning Escapement

To calculate spawning escapement, we assume one redd per female (Murdoch et al. 2009) and multiply the number of redds by the sex ratio of the pre-spawning population that was collected at the adult trap (i.e., no carcass collection bias issues). This should provide a more accurate expansion method than simply applying a constant value based on assumptions, or data from other studies, since it incorporates the natural variability that occurs in most populations (Murdoch et al. 2010). Because spawner distribution of hatchery and natural origin fish may be different, we expanded the natural and hatchery fish by reach [Wilderness, HMA (above trap), HMA (below trap), Hartsock, Marengo, and below Marengo] based on carcass recoveries. The total for all reaches equals the spawning escapement.

Sex ratio from the adult trap was only available from 2000 to present. For 1985 to 1999, we used corrected carcass data based on the methodology of Murdoch et al. (2010). For years when the corrected carcass data produced clear outliers, or produced spawning escapements greater than the run escapement we used data cited by Meekin (1967) that cited an average of 2.20 adults/redd and proportionately adjusted that figure up during years with high jack returns. The spawning escapement for 2016 was 340 fish (114 natural-origin, 226 hatchery-origin) based on 2.21 fish per redd. The estimated spawning escapement for 1985 to 2016 is found in Table 12.

Table 12. Estimated spawning escapement and the calculation methodology used for the 1985 to 2016 run years.

^a The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2015).

Coded-Wire Tag Sampling

Broodstock collection, pre-spawn mortalities, and carcasses recovered during spawning ground surveys provide representatives of the annual run that can be sampled for CWT study groups (Table 13). In 2016, based on the estimated escapement of fish to the river, we sampled approximately 52% of the run (Table 14).

Table 13. Coded-wire tag codes of hatchery salmon sampled at LFH and the Tucannon River, 2016.

Stray Salmon into the Tucannon River

Spring Chinook from other river systems (strays) are periodically recovered in the Tucannon River, though generally at a low proportion of the total run (Bumgarner et al. 2000). However, Umatilla River hatchery strays accounted for 8 and 12% of the total Tucannon River run in 1999 and 2000, respectively (Gallinat et al. 2001). Increased strays, particularly from the Umatilla River, was a concern since it exceeded the 5% stray proportion of hatchery fish deemed acceptable by NOAA Fisheries, and was contrary to fish management intent for the Tucannon River. In addition, the Oregon Department of Fish and Wildlife (ODFW) and the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) did not mark a portion of Umatilla River origin spring Chinook with an RV or LV fin clip (65-70% of releases), or CWT for the 1997-1999 brood years. Because of that action, some stray fish that returned from those brood years were physically indistinguishable from natural origin Tucannon River spring Chinook. Scale samples were collected from adults in those brood years to determine hatchery-origin fish based on scale pattern analysis. However, we are unable to differentiate between unmarked Tucannon fish and unmarked strays based on scale patterns. Beginning with the 2000 BY, Umatilla River hatchery-origin spring Chinook were 100% marked (adipose clipped), however, the implementation of a "stepping stone" hatchery management protocol for the Umatilla Hatchery Program has resulted in a portion of Umatilla Hatchery releases being unclipped beginning with the 2009 BY. This hinders our ability to selectively remove stray hatchery fish during broodstock collection, or from fish passed upstream at the TFH adult trap. We will continue to monitor the Tucannon River and emphasize the need for external marks and CWTs for Umatilla River releases.

Forty-three strays (one Clearwater River, 18 Umatilla River, and 24 AD clip/no wire) were recovered during 2016 (Appendix E). Nineteen strays were killed outright at the trap (two CWT 090729 and 17 AD clip/no wire), ten were recovered during spawning ground surveys (one CWT 090861, one CWT 090733, six CWT 090719, one CWT 220134, and one AD clip/no wire), nine were killed outright from the adult outplant group (three CWT 090719 and six AD clip/no wire), and five were inadvertently collected for broodstock (three CWT 090719 and two CWT 090652)]. After expansions, strays accounted for an estimated 10.0% of the total 2016 run (Appendix E).

The increased use of passive integrated transponder (PIT) tags by fish and wildlife agencies and the utilization of in-stream PIT tag arrays in the Tucannon River have permitted us to identify the origin of some spring Chinook PIT tagged from other locations during 2016. A total of thirty-five fish originally PIT tagged at locations other than the Tucannon River were detected in the Tucannon River (Table 15). The majority of these fish (30) were of unknown origin that were tagged as adults at Lower Granite Dam and eventually returned back downstream and entered the Tucannon River (Table 15). These fish could be Tucannon origin fish that overshot the river and returned back, however their actual origin is unknown. However, based on detection histories from three of the four strays detected in the Tucannon River that were also detected at Lower Granite Dam, these unknown origin fish could just as likely be stray spring Chinook from other basins. Two PIT tagged strays were detected at the Upper Tucannon River array (John Day and Walla Walla river origin), and three were detected at the Lower Tucannon River array (John Day, Selway, and Umatilla river origin) (Table 15).

Table 15. Tucannon River PIT tag array detections of spring Chinook originally tagged at locations other than the Tucannon River during 2016.

^a PIT tag array locations are as follows: LTR – Lower Tucannon River (rkm 2.2), MTR – Middle Tucannon River (rkm 17.8), UTR – Upper Tucannon River (rkm 44.4), TFH – Tucannon Fish Hatchery (rkm 59.2).

^b These fish were detected at Lower Granite Dam before falling back and entering the Tucannon River.

^c This fish was detected in the Tucannon but left and was detected in the Imnaha River.

Tucannon River Spring Chinook in Asotin Creek

The Major Population Group (MPG) for the lower Snake River includes only the Tucannon River and Asotin Creek populations; both must be viable for ESA recovery of this MPG (or the Tucannon population must be highly viable). The Asotin Creek population is considered to be functionally extirpated (SRSRB 2011). Based on genetic analysis of spring Chinook sampled from Asotin Creek (Blankenship and Mendel 2010), Tucannon River spring Chinook salmon are known to stray to Asotin Creek and contribute to population genetics. To assess the extent of this behavior, we conduct annual spring Chinook spawning ground surveys on Asotin Creek.

Asotin Creek Field Office staff did not capture any adult spring Chinook at the Asotin Creek weir before the weir was removed on 3 June, 2016 due to declining flows and increasing stream temperatures (Ethan Crawford, WDFW, personal communication). One natural origin PIT tagged spring Chinook salmon was detected at a PIT tag array near the mouth of Asotin Creek during 2016. This fish was PIT tagged at Lower Granite Dam on 10 May 2016 and was detected on 15 May 2016. This fish was not detected at an upstream array so it may have returned back to the Snake River. Snake River Lab and Asotin Creek Field Office staff surveyed known spring Chinook spawning areas in Asotin Creek (rkm 14.6-41.3) on 21 and 22 September, 2016. Two redds and one live fish were observed during 2016, however the section from Lick Creek (rkm 28.6) to the Confluence Bridge (rkm 27.0) was not surveyed, so redds and/or fish may have been missed (Table 16). Historical redd numbers for Asotin Creek are found in Table 17.

From the detected returns, 115 (22%) of the returning PIT tagged spring Chinook were detected upstream of the Tucannon River (Table 19; Appendix F). Thirty-six of these fish (7%) had their last detections at or above Lower Granite Dam (Table 19; Appendix F). The overshoot rate has decreased over time and it is unknown whether this is related to changes in smolt release methods (from direct release to acclimation ponds with volitional release), changes in hydropower operations and river flows, changes in the proportion barged downstream, increases in tagging numbers/sample size, or greater detection capabilities in the Tucannon River (Table 19). This does not appear to be a hatchery effect as both natural and hatchery origin fish overshoot the Tucannon River (Table 19). Non-direct homing behavior has been documented for adult Chinook in the Columbia River System (Keefer et al. 2008), and similar percentages of

natural origin spring Chinook from the John Day River have been documented bypassing that river (Jim Ruzycki, ODFW, personal communication). However, more research into these events should be conducted to examine whether they are natural straying occurrences, or if it is related to hydropower operations. The installation of PIT tag arrays in the Tucannon River during the past few years [Lower Tucannon River (LTR) at rkm 2.2 - 2005, Middle Tucannon River (MTR) at rkm 17.8 and Upper Tucannon River (UTR) at rkm 44.4 - 2011, and Tucannon Fish Hatchery (TFH) at rkm 59.2 – 2012] have enabled us to document that the majority of the Tucannon spring Chinook that overshoot are able to make it back (about 75%) to the Tucannon River (Table 19). Returning spring Chinook overshooting the Tucannon River continues to be a concern, especially if they are unable to return to the Tucannon River, or if they return in a more compromised state (i.e., injuries from additional dam crossings), and may partially explain why this population has been slow to respond to recovery and supplementation actions.

Table 19. Number and origin of PIT tagged Tucannon River spring Chinook returns that overshoot the Tucannon River (includes fish that were last detected returning back downstream towards the Tucannon River) and also detected at Lower Granite Dam (LGR) that stayed above LGR Dam. Years with installed in-stream PIT tag arrays (2005-2015) are included for comparison.

Juvenile Salmon Evaluation

Hatchery Rearing, Marking, and Release

Supplementation juveniles (249,357) were tagged with CWT (63/70/39) from 8 March to 16 March, 2016. Fish were transferred from LFH to TFH between 12 and 19 October, 2015. Fish were PIT tagged (target 15,000) for outmigration survival and adult return estimates on 26 January 2017. The target release size was increased from 30 g fish (15 fpp) to 38 g fish (12 fpp) beginning with the 2011 BY based on higher survival estimates through the hydropower system and greater adult returns for larger fish from the size at release study.

Brood year 2015 fish were sampled twice by Evaluations staff during the rearing cycle (Table 20). During February, a total of 1,801 fish were sampled for precocity and mark quality and 261 were sampled for length and weight statistics. The 2015 BY fish were transferred to Curl Lake AP on 15-17 February 2017 for acclimation and volitional release. Length, weight, and precocity samples were repeated in April at Curl Lake AP prior to release (Table 20).

Table 20. Sample size (N), mean length (mm), coefficient of variation (CV), condition factor (K), mean weight (g), and precocity of 2015 BY juveniles sampled at TFH, and Curl Lake AP.

	Sample	N .T	Mean	OT.	T 7	Mean	%
Date	Location	N	Length (mm)	\mathbf{CV}	K	Wt. (g)	Precocity
2/07/17	TFH	261	136.6	14.9	1.24	33.5	1.05
4/03/17	Curl Lake	275	143.2	11.3	1.31	39.5	0.36

A new fence was constructed around Curl Lake AP during the spring of 2015 after reports from hatchery staff of increased numbers of predators (primarily river otters) consuming hatchery fish. A PIT tag array was installed at the outlet of Curl Lake AP in 2014 in order to obtain a more accurate release number due to the high predation and was used again for release estimates during the spring of 2017. Interference caused by two or more PIT tags passing by the detectors at one time, also known as PIT tag "collisions", is a problem at the array so estimated release numbers should be considered minimal estimates. The release number will be adjusted in the future after previously undetected tags are detected along the outmigration corridor and an updated final release number will be reported in the historical hatchery releases (Appendix G) in the next annual report. Volitional release began 4 April and continued until 21 April when the remaining fish were forced out. Estimated numbers and size of fish released are provided in Table 21.

Table 21. Preliminary spring Chinook salmon releases into the Tucannon River, 2017 release year.

Release	CWT	Total	Number	VIE	Size		
Date	Code	Released	CWT	Mark	Total (kg)	Mean (g)	
4/04-4/21	63/70/39	199,686	187,601	None	7,883	40	

Smolt Trapping

Evaluation staff operated a 1.5 m rotary screw trap at rkm 3 on the Tucannon River from 13 October 2015 through 8 July 2016 to estimate numbers of migrating juvenile natural and hatchery spring Chinook. Numbers of each fish species captured by month during the 2016 outmigration can be found in Appendix H. The main outmigration of natural origin spring Chinook for the 2015/2016 outmigration occurred during the spring, with a very limited outmigration during the fall and winter months (Figure 7). Prior years have shown more outmigration in the fall and winter (Gallinat and Ross 2014, Gallinat and Ross 2015), although even in those years, the majority of the outmigration occurred in the spring.

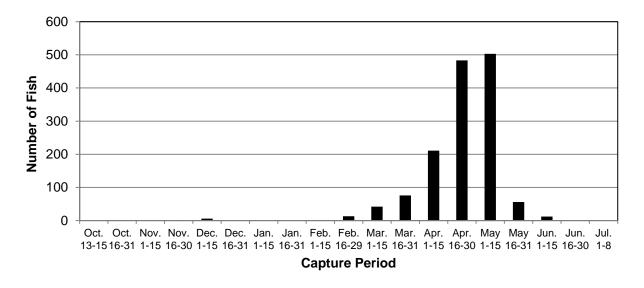

Figure 7. Emigration timing of natural spring Chinook salmon captured during smolt trap operations (rkm 3) on the Tucannon River for the 2015-16 migration year.

Natural spring Chinook emigrating from the Tucannon River (BY 2014) averaged 103 mm (Figure 8). This is in comparison to a mean length of 146 mm for hatchery-origin fish (BY 2014) released from Curl Lake Acclimation Pond (Gallinat and Ross 2015).

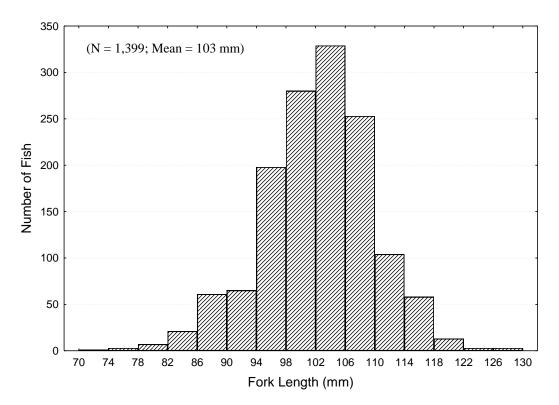

Figure 8. Length frequency distribution of sampled natural spring Chinook salmon captured in the Tucannon River smolt trap, 2015/2016 season.

Each week we attempted to determine trap efficiency by clipping a portion of the caudal fin on a representative subsample of captured migrants and releasing them approximately one kilometer upstream. The percent of marked fish recaptured was used as an estimate of weekly trapping efficiency. In previous reports we attempted to relate trap efficiency to abiotic factors such as stream flow or staff gauge level based on similar juvenile outmigration studies (Groot and Margolis 1991; Seiler et al. 1999; Cheng and Gallinat 2004). We found no significant relationships.

To estimate potential juvenile migrants passing when the trap was not operated for short intervals (≤ 5 days), such as periods when freshets washed out large amounts of debris from the river, we calculated the mean number of fish trapped for three days before and three days after non-trapping periods. The mean number of fish trapped daily was then divided by the estimated trap efficiency to calculate fish passage. The estimated number of fish passing each day was then applied to each day the trap was not operated.

We estimated outmigration based on the approach of Steinhorst et al. (2004). This involved using a Bailey-modified Lincoln-Peterson estimation with 95% bootstrap confidence intervals by running the Gauss Run-Time computer program (version 7.0). Bootstrap iterations numbered

1,000. The program allows for the division of the out-migration trapping season into strata with similar capture efficiencies as long as at least seven marked recaptures occurred. Strata with less than seven recaptures were grouped with either the preceding or following strata, depending upon similarity in trapping/flow conditions. Where river conditions were similar, we used our best judgment to group the strata. The majority of the historical emigration estimates did not have confidence limits around the estimates, and if they did, they were calculated using a different method. To standardize estimates, when possible, we re-calculated emigration estimates from the historical database using the approach of Steinhorst et al. (2004). Revised historical emigration estimates for spring Chinook salmon are found in Appendix I.

A number of assumptions are required to attain unbiased estimates of smolt production. How well the assumptions are met will determine the accuracy and precision of the estimates. Some of these assumptions are:

- Survival from release to the trap was 100%.
- All marked fish are identified and correctly enumerated.
- Fish do not lose their marks.
- All fish in the tag release group emigrate (i.e., do not residualize in the area of release).
- Marked fish are caught at the same rate as unmarked fish.

Accurate outmigration estimates are critical for describing survival trends and to measure population response to management actions such as hatchery supplementation and habitat restoration. It has been strongly suggested that researchers test the assumptions of population estimators being used (Peterson et al. 2004; Rosenberger and Dunham 2005). Other WDFW researchers have identified bias in smolt trap efficiency estimates that were conducted similarly to Tucannon River trap efficiency tests. While the evidence of estimator bias and error seem consistent in the literature, our methods differ from those, and must be tested to estimate the level of error, and confirm compliance of the methods with underlying assumptions. If bias in our methods has been consistent over the term of the data, data could be adjusted as appropriate once bias is measured.

In past years, we attempted to measure bias in our efficiency estimates through the use of PIT tags and the PIT tag array that has been deployed in the lower Tucannon River below the smolt trap. Representative groups of fish were fin clipped and PIT tagged to determine smolt trap efficiency based on either recaptures in the smolt trap or detections by the PIT tag array in the Tucannon River. However, the PIT tag array proved unreliable in its detection of juvenile salmonids. If PIT tag technology in the future allows for greater detections of juvenile salmonids, then we will attempt to measure trapping bias again. We estimate that 6,604 (S.E.

517.0; 95% C.I. 5,674-7,696) migrant natural-origin spring Chinook (2014 BY) passed the smolt trap during 2015-2016.

Juvenile Migration Studies

In 2016, we used PIT tags to study the emigration timing and relative success of our hatchery supplementation smolts. A total of 14,983 hatchery supplementation fish were PIT tagged during January before transferring them to Curl Lake AP for acclimation and volitional release (Table 22). Cumulative PIT tag detections at hydroelectric projects downstream of the Tucannon River were 48% (Table 22).

Table 22. Cumulative detection (one unique detection per tag code) and mean travel time in days (TD) of PIT tagged conventional hatchery supplementation smolts released from Curl Lake AP (rkm 65.6) on the Tucannon River at downstream Snake and Columbia River dams during 2016.

-	Re	elease Dat	a		Recapture Data											
		Mean		Mean	LN	ЛJ	I	СН	M	CJ	J	DJ	ВО	NN	Tot	tal ^b

Hatch.	14,983	133.2	18.1	133.5	2139	15.8	421	18.5	1255	21.2	693	21.1	125	24.5	7,187	48.0

^a Fish were volitionally released from 4/01/16 - 4/15/16.

^b Includes fish detected at the lower Tucannon River PIT tag array (LTR) and trawl detections below Bonneville Dam (TWX). Note: Mean travel times listed are from the total number of fish detected at each dam, not just unique recoveries for a tag code. Abbreviations are as follows: LMJ-Lower Monumental Dam, ICH- Ice Harbor Dam, MCJ-McNary Dam, JDJ-John Day Dam, BONN-Bonneville Dam, TD- Mean Travel Days.

Survival Rates

Point estimates of population sizes have been calculated for various life stages (Tables 23 and 24) of natural and hatchery-origin spring Chinook from spawning ground and juvenile mid-summer population surveys, smolt trapping, and fecundity estimates. Survivals between life stages have been calculated for both natural and hatchery salmon to assist in the evaluation of the hatchery program. These survival estimates provide insight as to where efforts should be directed to improve not only the survival of fish produced within the hatchery, but fish in the river as well.

As expected, juvenile (egg-parr-smolt) survival rates for hatchery fish are considerably higher than for naturally reared salmon (Table 25) because they have been protected in the hatchery. However, SARs to the Tucannon River of natural salmon were over seven times higher (based on geometric means) than for hatchery-reared salmon (Tables 26 and 27). With the exception of the 2006 brood year, hatchery SARs (mean 0.25%; geometric mean 0.16%) documented from the 1985-2011 broods have been well below the LSRCP survival goal of 0.87%. Hatchery SARs for Tucannon River salmon need to substantially improve to meet the mitigation goal of 1,152 hatchery adult salmon. The target size at release was increased to 38 g fish (12 fpp) beginning with the 2011 brood year in an attempt to improve smolt-to-adult return survival rates.

Table 23. Estimates of *natural in-river produced* Tucannon spring Chinook salmon (both hatchery and natural origin parents) abundance by life stage for 1985-2016 broods.

2016	53	101	3,704	3,179	517,391			

^a 1985 and 1989 mean fecundity of natural females is the average of 1986-88 and 1990-93 brood years.

^b Number of parr estimated from electrofishing (1985-1989), Line transect snorkel surveys (1990-1992), and Total Count snorkel surveys (1993-2005).

^c Numbers do not include down river harvest or other out-of-basin recoveries.

^d The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2016).

^e Smolt estimates could not be estimated with the GAUSS program for the 1991 and 1995 brood years. Numbers of smolts for those brood years were obtained from estimates in the annual reports.

Table 24. Estimates of Tucannon spring Chinook salmon abundance (*spawned and reared in the hatchery*) by life stage for 1985-2016 broods.

								Progeny

2016	31	41	3,704	3,179	245,174	230,106	,	

^a 1985 and 1989 mean fecundity of natural females is the average of 1986-88 and 1990-93 brood years; 1999 mean fecundity of natural fish is based on the mean of 1986-1998 brood years.

b Numbers do not include down river harvest or other out-of-basin recoveries.

^c Number of smolts is less than actual release number. 57,316 parr were released in October 1993, with an estimated 7% survival. Total number of hatchery fish released from the 1992 brood year was 140,725. We therefore use the listed number of 87,752 as the number of smolts released.

^d Parr determined to be in excess of program goals were released at Russell Springs and are not included in number of parr and smolts.

^e Temporary estimate based on PIT tag detections at the Curl lake PIT tag array. A final estimate will be provided in the 2017 annual report.

Table 25. Percent survival by brood year for juvenile salmon and the multiplicative advantage of hatchery-reared salmon over naturally-reared salmon in the Tucannon River.

^a Expanded numbers are calculated from the proportion of each known age salmon recovered in the river and from broodstock collections in relation to the total estimated return to the Tucannon River. Expansions do not include down river harvest or Tucannon River fish straying to other systems.

b One known (expanded to two) Age 6 salmon was recovered.

^c Numbers of smolts obtained from estimates in the annual reports.

d The 2011 and 2012 SARs are not included in the mean.

Table 27. Adult returns and SARs of hatchery salmon to the Tucannon River for brood years 1985-2013. (2012 and 2013 are incomplete brood years included for comparison.)

Expanded numbers are calculated from the proportion of each known age salmon recovered in the river and from broodstock collections in relation to the total estimated return to the Tucannon River. Expansions do not include down river harvest or Tucannon River fish straying to other systems.

As previously stated, overall survival of hatchery salmon to return as adults was higher than for naturally reared fish because of the early-life survival advantage (Table 25). With the exception of eleven brood years (39%), naturally produced fish have been below the replacement level (Figure 9; Table 28). Based on adult returns from the 1985-2012 broods, naturally reared salmon produced only 0.76 adults for every spawner, while hatchery reared fish produced 2.02 adults (based on geometric means).

b The 2011 and 2012 SARs are not included in the mean.

Beginning with the 2006 brood year, the annual smolt goal was increased from 132,000 to 225,000 to help offset for the higher mortality of hatchery-origin fish after they leave the hatchery. This should increase adult salmon returns back to the Tucannon River. However, based on current hatchery SARs the increase in production would still not produce enough adult returns to reach the LSRCP mitigation goal. Hatchery production changes that result in

increased survival/return numbers may result in a Proportionate Natural Influence (PNI) of less than 0.5. This level is generally not considered acceptable for supplementation programs. Historically the PNI for the Tucannon Spring Chinook Program has generally been above 0.5 (Appendix J).

The long-term restoration goal for the State of Washington is to provide a total annual return of between 2,400-3,400 hatchery and natural origin fish back to the Tucannon River (SRSRB 2006) that should include at least 750 natural origin fish over a 10-year geometric mean (population viability threshold) (ICTRT 2008). Natural origin returns had been increasing in recent years (Figure 10), but decreased in 2016. However, we are still below the 10-year moving geometric mean of 750 natural origin fish.

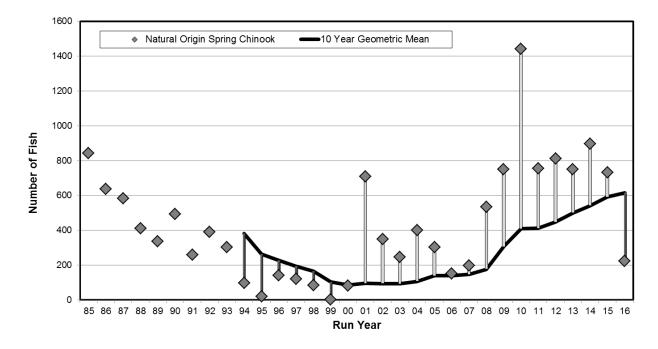

Figure 10. Tucannon River spring Chinook natural origin returns with the moving ten year geometric mean (black line) for the 1985-2016 run years.

Fishery Contribution and Out-of-Basin Straying

An original goal of the LSRCP supplementation program was to enhance returns of salmon to the Tucannon River by providing 1,152 adult hatchery origin fish (the number estimated to have been lost to the project area due to the construction and operation of the Lower Snake River hydropower system) to the river from hatchery-reared smolt releases. Such an increase would allow for limited harvest and increased spawning. However, hatchery adult returns have always been below the mitigation goal (Figure 11). Based on CWT recoveries reported to the Regional Mark Information System (RMIS) database (Appendix K), sport, commercial, and treaty ceremonial harvest combined accounted for an average of less than 6% of the adult hatchery fish recovered for the 1985-1996 brood years. Increased fishery impacts occurred for the 1997 through 1999 broods when the states implemented mark-selective fisheries in the lower Columbia River (fishery harvest comprised an average of 19% for recoveries). We subsequently stopped adipose fin clipping of hatchery production (Gallinat et al. 2001) to lessen non-tribal fishery impacts. Returning hatchery adults are now just tagged with CWTs, but do not have external marks to identify them as hatchery origin fish. This has resulted in lower sport fishery impacts. Based on CWT recoveries for the 2000-2012 brood years, harvest (primarily commercial) has accounted for only 6% of the hatchery adult CWT recoveries (Appendix K).

Out-of-basin stray rates of Tucannon River spring Chinook have generally been low (Appendix K), with an average of 1.2% of the adult hatchery fish straying to other river systems/hatcheries for brood years 1985-2013 (range 0-20%).

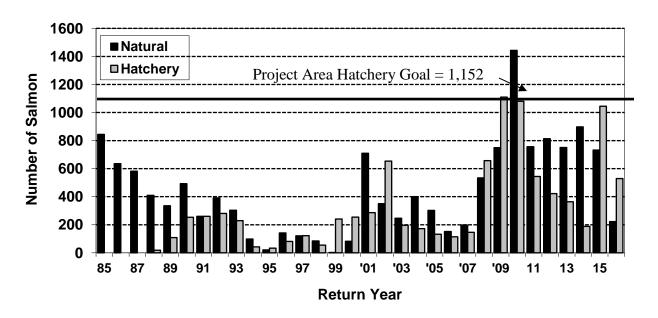

Figure 11. Total escapement for Tucannon River spring Chinook salmon for the 1985-2016 run years.

Adjusted Hatchery SAS

Using CWT recoveries from the RMIS database, we adjusted Tucannon River spring Chinook hatchery smolt-to-adult survival (SAS) to include all known recoveries both from within and outside the Tucannon River. Increased fishing mortality resulted in higher adjusted SAS for the 1997, 1998, and 2006 brood years. With minor exceptions (1997 and 2006 brood years), even after adjustment, hatchery SAS were still well below the LSRCP survival goal of 0.87% (Table 29).

Table 29. Hatchery SAS adjusted for recoveries from outside the Tucannon River subbasin as reported in the RMIS database, 1985-2011 brood years. (Data downloaded from RMIS database on 3/13/17).

^a Includes expanded RMIS CWT recoveries from sources outside the Tucannon River subbasin (i.e., sport and commercial fisheries, Tucannon strays in other river systems, etc.).

LFH vs. TFH Reared Comparison

As mentioned earlier in this report, Tucannon River spring Chinook salmon that are collected for broodstock at the TFH adult trap are transported to LFH for holding and spawning, and incubation and early life rearing. This is primarily due to the availability of colder, pathogen free water and rearing space at LFH. However, during the review of the Tucannon River Spring Chinook Hatchery and Genetic Management Plan, the Hatchery Scientific Review Group recommended developing long-term rearing capabilities within the Tucannon River Subbasin as one of their recommendations for the hatchery program (HSRG 2009). This recommendation was based on questions that were raised as to whether rearing the hatchery fish for the majority of their early life at LFH affected their survival and ability to home back to the Tucannon River. To answer these questions, approximately 30,000 eggs were transferred to TFH for incubation and rearing for three brood years (BY11-13) for comparison to LFH reared fish (Appendix L). To avoid potential bias in recovery rates between the two release groups (Zhou 2002, Murdoch et al. 2010), we used PIT tag detections of migrating smolts and returning adults to compare performance and relative survival between the LFH reared and TFH reared groups of spring Chinook. Fish with PIT tags are detected through a network of interrogation systems currently in place in juvenile bypass systems and adult fishways at hydroelectric dams (Burke and Jepson 2006). In addition, small instream arrays have been developed to remotely detect PIT tagged fish (Zydlewski et al. 2006; Bond et al. 2007), and these units have been installed in the Tucannon River. Each group was tagged with a unique CWT and a subset (Target -7,500) of each group was PIT tagged (Table 30).

Juvenile Survival

Survival probabilities were estimated by the Cormack-Jolly-Seber methodology using the Survival Under Proportional Hazards (SURPH) 3.0 computer model. The data files were created using the PitPro (version 4.19.7) computer program to translate raw PIT Tag Information System (PTAGIS) data of the Pacific States Marine Fisheries Commission into usable capture histories for the SURPH program. To determine significant differences in survival probabilities between groups, we used the Likelihood Ratio Test statistic. Estimated survival probabilities from Curl Lake to Lower Monumental Dam were not significantly different (P > 0.05) between the two groups (Table 30).

Adult Returns

Returning PIT tagged detected fish were assumed to be mature the year they entered freshwater after being in the marine environment. We calculated the smolt-to-adult survival (SAS) as the total number of fish that were detected within the Columbia and Snake River watersheds (Table

31). Smolt-to-adult return (SAR) was calculated as the number of fish that were detected in the Tucannon River (Table 31). Returns for the 2012 and 2013 brood years are incomplete, but preliminary data does not show a significant benefit in either survival or homing back to the Tucannon River by rearing fish at TFH (Table 31). Unless future data shows a different result, we will continue to use LFH for holding and spawning, and incubation and early life rearing.

Table 30. Release number, size at release (g), and number of Tucannon River hatchery spring Chinook PIT tagged by brood year (BY) for each rearing location and SURPH survival probabilities from Curl Lake Acclimation Pond to Lower Monumental Dam for the 2011 to 2013 brood years.

TFH BY13	23	6			29	0.39%	4	0.05%

Conclusions and Recommendations

Washington's LSRCP hatchery spring Chinook salmon program has failed to return adequate numbers of adults to meet the mitigation goal. This has occurred because SARs of hatchery origin fish have been consistently lower than what was originally assumed under the LSRCP program development, even though hatchery returns (recruits/spawner) have generally been at 2-4 times the replacement level. However, because of the advantage in survival during early life history stages for fish in the hatchery, the progeny-to-parent ratio for hatchery produced fish has generally been above replacement and therefore may have sustained the population during years when the population was at critically low levels. We have seen a significant rebound of natural origin fish in recent years and we came close to reaching the within river hatchery (LSRCP) goal of 1,152 fish in 2009 and 2010. System survivals (in-river, migration corridor, and ocean) must increase in the near future for the hatchery program to succeed, the natural run to persist over the short-term, and the natural population to increase to a level where it can be sustainable over the long-term.

Until that time, the evaluation program will continue to document and study life history survivals, straying, carrying capacity, genotypic and phenotypic traits, and examine procedures within the hatchery that can be changed to improve the hatchery program and the natural population. Based on our previous studies and current data we recommend the following:

- 1. We continue to see annual differences in phenotypic characteristics of returning salmon (i.e., hatchery fish are generally younger and less fecund than natural origin fish), yet other traits such as run and spawn time are little changed over the program's history. Further, genetic analysis to date has detected little change in the natural population that may have resulted from hatchery actions.
 - <u>Recommendation</u>: Continue to collect as many carcasses as possible for the most accurate age composition data. Collect biological data (length, run timing, spawn timing, fecundity estimates, DNA samples, smolt trapping, and life stage survival) to document the effects (positive or negative) that the hatchery program may have on the natural population.
- 2. Based on annual redd densities and historical spring Chinook radio tag data, the Tucannon Fish Hatchery weir/trap has been an impediment to upstream passage of spring Chinook to the better spawning and rearing habitat upstream of the trap. Numerous options to improve attraction into the ladder/trap have been discussed with some recently implemented.
 - <u>Recommendation</u>: Monitor changes made to the ladder/trap to see if they improve passage for all fish species. If improvements are not seen, seek funding and engineering expertise to modify the design and/or operation of the weir/trap structure.

- 3. Subbasin and recovery planning for ESA listed species in the Tucannon River have identified factors limiting the spring Chinook population and strategies to recover the population.
 - <u>Recommendation</u>: Assist population conservation efforts by updating recent carrying capacity/density and straying effects, and productivity estimates of the Tucannon River so that hatchery stocking is appropriate, and hatchery and natural performance is measured against future basin capacity after habitat improvements.
- 4. We have documented that hatchery juvenile (egg-parr-smolt) survival rates are considerably higher than naturally reared salmon, and hatchery smolt-to-adult return rates are much lower. We need to identify and address the factors that limit hatchery SARs in order to meet mitigation goals and for natural production to meet recovery goals. Beginning with the 2006 brood year, the annual hatchery smolt goal was increased from 132,000 to 225,000 to help offset the higher mortality of hatchery-origin fish after they leave the hatchery. This should increase adult salmon returns back to the river, however, based on current mean hatchery SARs this would still not produce enough adult returns to reach the LSRCP mitigation goal.

<u>Recommendation</u>: Continue to evaluate survival rates from other reference watersheds to see if the LSRCP goal of 0.87% is a realistic goal under existing conditions. PIT tag natural origin fish in the river to ascertain where or at what life stage mortality is occurring. Utilize fish carcasses from hatchery operations for stream nutrient enrichment. Encourage fish and wildlife enforcement patrols and additional public education efforts during periods when spring Chinook adults are most vulnerable (pre-spawn and spawning).

5. Over the last few years, we have documented higher in-river pre-spawn mortality than what was observed historically. The mechanism for this higher loss is still unclear. However, the high loss has prompted drastic action within the program, whereby all, or the majority of the returns to the TFH trap between 2015 to 2017 have been collected and held at LFH for adult outplanting. Results from the first year (2015) of adult outplants appeared successful, with > 90% of the fish spawning, contrasted to 30% survival of fish left in the river. In 2016, it appeared that only about 55% of outplanted fish successfully spawned.

<u>Recommendation</u>: Continue to monitor high in-river pre-spawn mortality that has occurred in recent years. Continue intensive monitoring of adult outplants to determine spawning success. Weigh all pertinent information (pre-spawn mortality rates, outplant success, predicted run sizes, risk of holding all fish at one facility, etc.) and inform co-managers and NMFS on future adult outplants. An agreed upon threshold is needed to make the decision whether to pass fish at the adult trap or hold fish at LFH for outplanting.

Appendix A: Annual Takes for 2016

Appendix A. Table 1. Summary of permissible direct take and actual take (in parenthesis) of Snake River spring/summer Chinook salmon for RM&E activities associated with the Tucannon River spring Chinook salmon program not directly related to fish culture for the 2016 calendar year. NMFS must be notified

within two days if the number handled, tagged, or killed are exceeded.

Origin and lifestage Natural-origin	Take activity Capture, handle,	Capture method And location Trapping	Total number handled annually (0.5% handling mortalities)	Number of those handled that are marked/tagged annually (1% handling mortalities 7,000	Total number killed or removed annually Up to 160
juveniles	tag, tissue sample, and release live animal.	operations that include a screw trap, beach seines, cast nets, dip nets, and use of backpack electroshock equipment throughout the Tucannon River.	(1,461)	(1,429)	(5)
Hatchery-origin juveniles	Capture, handle, tag, tissue sample, and release live animal.	Trapping operations that include a screw trap, beach seines, cast nets, dip nets, and use of backpack electroshock equipment throughout the Tucannon River.	35,000 (11,550)	7,000 (2,066)	Up to 245 (22)
Natural-origin adults & jacks	Capture, handle, tag, tissue sample, and release live animal.	Adult and jack fall back at screw traps.	5 (0)	5 (0) (genetic fin-clip or operculum punch – release live.)	Up to 2 ^a (0)
Hatchery-origin adults & jacks	Capture, handle, tag, tissue sample, and release live animal.	Adult and jack fall back at screw traps.	10 (0)	10 (0)	Up to 2 ^a (0)

^a In cases where total number killed is not likely to exceed one (1) mortality, NMFS rounds the total mortality up to two (2), so that operations are not halted completely at the first mortality.

Appendix A. Table 2. Summary of permissible direct take and actual take (in parenthesis) of listed Snake River spring/summer Chinook salmon for fish culture purposes for the Tucannon River Spring Chinook salmon program for the 2016 calendar year. NMFS must be notified within two days if the number handled,

tagged, or killed are exceeded.

Origin and lifestage	Take activity	Capture method and location	Total number handled annually	Number of those handled that are marked/tagged annually (1% trap mortalities	Total number killed or removed annually
Natural-origin adults	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, remove for use for broodstock, or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	2,000 (116)	Up to 1,824 ^b (passed live with finclip or operculum punch, PIT and/or radio tagged) (4 passed upstream) (54 outplanted upstream)	Up to 232 ^b broodstock and fish used for outplants (55 broodstock) (3 A.O. PSM's) Plus up to 19 adult trap mortalities (0)
Natural-origin jacks	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, remove for use for broodstock, or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	200 (11)	Up to 200 (passed live with fin- clip or operculum punch, PIT and/or radio tagged) (2 passed upstream) (9 outplanted upstream)	Up to 9 broodstock. (0) Plus up to 2 trap mortalities.
Hatchery-origin adults	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, remove for use for broodstock, or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	1,400 ^b (up to 132 removed for broodstock based on sliding scale) (299)	Up to 1,400 ^b (passed live with finclip or operculum punch, PIT and/or radio tagged) (13 passed upstream) (175 outplanted upstream)	Up to 232 ^b broodstock and fish held for later outplanting. (71 broodstock) (28 A.O. PSM & KO) Up to 100% of total handled may be removed, killed, or transported as described in the HGMP (12 killed outright)
Hatchery-origin jacks	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, use for broodstock, remove for adult management or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	500 (169)	Up to 135 (more may be passed to mimic natural- origin jack proportions, with NMFS concurrence) (passed live with fin- clip or operculum punch) (6 passed upstream) (58 outplanted)	Up to 9 broodstock. (0) Up to 100% of remainder may be removed, transported, or killed for jack management as described in the HGMP (102 killed outright) (3 A.O. PSM & KO)
Hatchery-origin egg & juveniles	Capture, handle, tag, tissue sample, and release live animal (within hatchery sampling, and research use).	Tucannon Hatchery or Lyons Ferry Hatchery total	280,125 (245,174 - BY16) (Maximum eggs/juveniles on hand annually prior to any juvenile rearing loss)	280,125 (14,983 BY14 PIT tagged)	Up to 55,125 total rearing mortality (3,118 BY15) (15,949 BY16)
Hatchery-origin juveniles	Capture, sample, kill (fish health examinations)	Tucannon Hatchery or Lyons Ferry Hatchery total	170 (50)	170 (0)	170 (50)

^a In years when returns to Tucannon Hatchery are low, adult Chinook arriving at Lyons Ferry Hatchery ladder that are identifiable as Tucannon River hatchery adults may be taken for broodstock.

^b The actual number taken annually will be subject to the sliding scale in the HGMP, in addition to fish that are collected, held, and used for adult outplants in the Tucannon, but may die while holding, or be used as part of the broodstock, and shall not exceed the totals of each origin identified there.

Appendix B: Spring Chinook Captured, Transported to Lyons Ferry Hatchery, or Passed Upstream at the Tucannon Hatchery Trap in 2016

Appendix B. Spring Chinook salmon captured, transported to Lyons Ferry Hatchery, or passed upstream at the Tucannon Hatchery trap in 2016. (Trapping began in February; last day of trapping was September 30).

The expansion is based on subsample rates of the proportion of stray carcasses to Tucannon River origin carcasses from the river. Actual counts are not expanded.

Appendix E (continued). Summary of identified stray hatchery origin spring Chinook salmon that escaped into the Tucannon River (1990-2016).

 $^{- \,} Middle \, Tucannon \, River, \, UTR - Upper \, Tucannon \, River, \, LGO - Little \, Goose \, Dam, \, LGR - Lower \, Granite \, Dam, \, AFC - Asotin \, Creek.$

^a PIT tag adult detection systems were in operation beginning in 1988 for LGR, 1998 for BON, 2002 for MCN, 2005 for both ICH and LTR, 2011 for MTR and UTR, and 2012 for TFH.

^b This fish was detected bypassing the Tucannon River (LGO or LGR detection) before heading back downstream.

Appendix F (continued). Final PIT tag detections of returning Tucannon River spring Chinook from fish originally tagged as juveniles from the Tucannon River.

Release types are: Tucannon Hatchery Acclimation Pond (H-Acc); Portable Acclimation Pond (P-Acc); Curl Lake Acclimation Pond (C-Acc); and Direct Stream Release (Direct).

All tag codes start with agency code 63.

Codes listed in column are as follows: BWT - Blank Wire Tag; CB - Captive Brood; VI-Visual Implant (elastomer); LR - Left Red, RR -Right Red, LG-Left Green, RG - Right Green, LY - Left Yellow, RY - Right Yellow, LB - Left Blue, RB - Right Blue, LP - Left Purple; Oxytet. – Oxytetracycline Mark; Crosses: WxW - wild x wild progeny, HxH - hatchery x hatchery progeny, Mixed – wild x hatchery progeny. No tag loss data due to presence of both CWT and BWT in fish.

VI tag only.

No wire.

g Smolt release numbers were estimated with a PIT tag array at the outlet of Curl Lake AP and will be finalized in the 2017 annual report.

^a This estimate is from Seidel et al. 1988.

^b Due to the lack of an ESA Section 10 Permit, the smolt trap had to be pulled.

^c Estimates were not available due to too few recaptures during trap efficiency trials.

Appendix J. Proportionate Natural Influence (PNI)^a for the Tucannon River spring Chinook population

(1985-2016). Note: Pre-spawn and trap mortalities are excluded from the analysis.

 $^{^{}a}$ PNI = PNOB/(PNOB + PHOS).

PNOB = Percent natural origin fish in the hatchery broodstock.

PHOS = Percent hatchery origin fish among naturally spawning fish.

Appendix K: Recoveries of Coded-Wire Tagged Salmon Released Into the Tucannon River for the 1985-2013 Brood Years

Appendix K. Observed and estimated recoveries of coded-wire tagged salmon released into the Tucannon River with percent return to the Tucannon Basin, out-of-basin returns, and estimated survival and exploitation rates for the 1985-2013 brood years. (Data downloaded from RMIS database on 3/13/17.)
