August 2019

Acknowledgments

The Tucannon River Spring Chinook Salmon Hatchery Evaluation Program is the result of efforts by many individuals within the Washington Department of Fish and Wildlife (WDFW) and from other agencies.

We would like to express our gratitude to Ace Trump, Lyons Ferry Hatchery Complex Manager and Hatchery Specialists Steve Jones, Dan Pounds, Doug Maxey, and Derek Gloyn for their cooperation with hatchery sampling, providing information regarding hatchery operations and hatchery records, and their input on evaluation and research activities. We also thank all additional hatchery personnel who provide the day-to-day care of the spring Chinook and for their assistance with hatchery spawning, sampling, and record keeping.

We thank Andrew Claiborne for providing scale ages and Kelly Britt for providing information on fish health during the year. Special thanks go to David Bramwell for help formatting this report.

We thank the staff of the Snake River Lab; in particular, Joe Bumgarner, Ashly Beebe, Sarah Golden, Todd Miller, Afton Oakerman, Lance Ross and seasonal workers Justin Byers, Conner Girardin, Ashish Katru, Jarrod Miller, Daniel Olson, and Eric Randell who helped collect the information presented in this report.

We thank Joe Bumgarner, Alf Haukenes, Rod Engle, and Lance Campbell for reviewing the draft report.

The United States Fish and Wildlife Service through the Lower Snake River Compensation Plan Office funds the supplementation program. A grant through the Bonneville Power Administration provided funding for a portion of the hatchery program PIT tags.

Abstract

Lyons Ferry Hatchery (LFH) and Tucannon Fish Hatchery (TFH) were built/modified under the Lower Snake River Fish and Wildlife Compensation Plan. One objective of the Plan is to compensate for the estimated annual loss of 1,152 Tucannon River spring Chinook caused by hydroelectric projects on the Snake River. This report summarizes activities of the Washington Department of Fish and Wildlife Lower Snake River Hatchery Evaluation Program for Tucannon River spring Chinook for the period May 2018 to April 2019.

A total of 431 salmon were captured in the TFH trap in 2018 (62 natural adults, 11 natural jacks, 297 hatchery adults, and 61 hatchery jacks). Of these, 160 adults (37 natural, 123 hatchery) were collected and hauled to LFH for broodstock, 38 adipose clipped strays were killed outright, 18 were passed upstream (15 natural, 3 hatchery), and the remaining fish (215) were held at LFH for adult outplanting. During 2018, 20 (12.5%) salmon collected for broodstock died prior to spawning.

Spawning of supplementation fish occurred once a week between 28 August and 18 September, with peak eggtake occurring on 11 September. A total of 212,973 eggs were collected from 9 natural and 67 hatchery-origin female Chinook. Egg mortality to eye-up was 3.1% (6,639 eggs) which left 206,334 live eggs. An additional 0.95% (1,970) loss of sac-fry left 204,364 BY 2018 fish for production.

Weekly spawning ground surveys were conducted from 21 August and were completed by 1 October 2018. A total of 109 redds and 67 carcasses (9 natural, 58 hatchery) were found. Seventy-seven redds (76% of the total) were counted above the adult trap. Based on redd counts, carcasses recovered, and broodstock collection, the estimated return to the river for 2018 was 545 spring Chinook (80 natural adults, 0 natural jacks and 425 hatchery-origin adults, 40 hatchery jacks).

Volitional release of the 2017 BY smolts began on 4 April and continued until 3 May, 2019 when the remaining fish were forced out. An estimated 144,219 BY17 smolts were released.

Evaluation staff operated a downstream migrant trap to provide juvenile outmigration estimates. During the 2017/2018 emigration, we estimated that 8,058 (4,618-16,014 95% C.I.) natural spring Chinook (BY 2016) smolts emigrated from the Tucannon River.

Smolt-to-adult return rates (SAR) for natural origin salmon are almost eight times higher on average (based on geometric means) than hatchery origin salmon. However, hatchery salmon

survive almost three times greater than natural salmon from parent to adult progeny over the length of the project.

A study was conducted for three brood years (BY11-13) to determine if rearing full term at TFH would return more adults back to the Tucannon River versus the current protocol of egg incubation and early life rearing at LFH. This study concluded with the final adult returns in 2018. Results from PIT tag detections did not show a significant benefit in either survival or homing back to the Tucannon River by rearing fish at TFH instead of LFH. Based on the findings, we will continue to use LFH for holding, spawning, and incubation and early life rearing of Tucannon River spring Chinook.

Introduction

Program Objectives

Legislation under the Water Resources Act of 1976 authorized the establishment of the Lower Snake River Compensation Plan (LSRCP) to help mitigate for the losses of salmon and steelhead runs due to construction and operation of the Snake River dams and authorized hatchery construction and production in Washington, Idaho, and Oregon as a mitigation tool (USACE 1975). In Washington, Lyons Ferry Hatchery (LFH) was constructed and Tucannon Fish Hatchery (TFH) was modified. Under the mitigation negotiations, local fish and wildlife agencies determined through a series of conversion rates of McNary Dam counts that 2,400 spring Chinook (2% of passage at McNary Dam) annually escaped into the Tucannon River. The agencies also estimated a 48% cumulative loss rate to juvenile downstream migrants passing through the four lower Snake River dams. As such, 1,152¹ lost adult Tucannon River origin spring Chinook needed to be compensated for above the project area, with the expectation that the other 1,248 (52%) would continue to come from natural production. An additional 4,608 were originally assumed to have been harvested in downriver fisheries or in the ocean, and was an additional objective of the plan. The agencies also determined through other survival studies at the time that a smolt-to-adult survival rate (SAR) to the project area of 0.87% was a reasonable expectation for spring and summer Chinook salmon. Based on an assumed 0.87% above project area SAR and the 1,152 above project area mitigation goal it was determined that 132,000 smolts needed to be released annually. In 1984, Washington Department of Fish and Wildlife² (WDFW) began to evaluate the success of these two hatcheries in meeting the mitigation goal, and identifying factors that would improve performance of the hatchery fish.

In an attempt to increase adult returns and come closer to achieving the LSRCP mitigation goal, the co-managers agreed to increase the conventional supplementation program goal to 225,000 yearling smolts annually beginning with the 2006 brood year. Size at release was increased to 38 g fish [12 fish/lb (fpp)] beginning with the 2011 brood year. This report summarizes work performed by the WDFW Tucannon Spring Chinook Evaluation Program from May 2018 through April 2019.

¹The project area escapement is 1,152. It was also assumed that four times that number (4,608 fish) would be harvested below the project area. Here "project area" is defined as above Ice Harbor Dam.

² Formerly Washington Department of Fisheries.

ESA Permits

The Tucannon River spring Chinook population was originally listed as "endangered" under the Endangered Species Act (ESA) on April 22, 1992 (FR 57 No. 78: 14653). The listing status was changed to "threatened" in 1995 (April 17, 1995; FR 60 No. 73: 19342). The listing was reviewed again in 1999 (FR 64 (57): 14517-14528) with the population remaining listed as "threatened" as part of the Snake River Spring/Summer Chinook Salmon evolutionary significant unit (ESU). The WDFW was originally issued a Section 10 Permit (#848 – broodstock collection and monitoring) which expired in March 1998. Permits #1126 and #1129 were issued in 1998 to allow continued take for this program, but those permits have since expired. A Hatchery and Genetic Management Plan (HGMP) was originally submitted as the application for a new Section 4 (d) Permit for this program in 2005. An updated HGMP requesting ESA Section 10 permit coverage was submitted in 2011, and was approved in 2016 (Permit #18024). This annual report summarizes all work performed by WDFW's LSRCP Tucannon Spring Chinook Salmon Evaluation Program during 2018. Numbers of direct and indirect takes of listed Snake River spring Chinook (Tucannon River stock) for the 2018 calendar year are presented in Appendix A (Tables 1-2), along with information required for the NEOR/SEWA Biological Opinion reporting.

Facility Descriptions

Lyons Ferry Hatchery is located on the Snake River (rkm 90) at its confluence with the Palouse River and has eight deep wells that produce nearly constant 11° C water (Figure 1). It is used for adult broodstock holding and spawning, and early life incubation and rearing. All juvenile fish are marked and returned to TFH in late September/October for final rearing and acclimation.

Tucannon Fish Hatchery, located at rkm 59 on the Tucannon River, has an adult collection trap on site (Figure 1). Adults returning to TFH are transported to LFH and held until spawning. Juveniles are reared at TFH through the winter on a combination of well, spring, and river water. River water is the primary water source, which allows for a more natural winter temperature profile. In February/March, the fish are transported to Curl Lake Acclimation Pond (AP) located at rkm 66, a 0.85-hectare natural bottom lake with a mean depth of 2.7 m, with the smolts volitionally released during April.

Tucannon River Watershed Characteristics

The Tucannon River empties into the Snake River between Little Goose and Lower Monumental Dams approximately 622 rkm from the mouth of the Columbia River (Figure 1). Stream elevation rises from 150 m at the mouth to 1,640 m at the headwaters (Bugert et al. 1990). Total

watershed area is approximately 1,295 km². Local habitat problems related to logging, road building, recreation, and agriculture/livestock grazing have limited the production potential of spring Chinook in the Tucannon River. Land use in the Tucannon watershed is approximately 36% grazed rangeland, 33% dry cropland, 23% forest, 6% WDFW, and 2% other use (Tucannon Subbasin Summary 2001). Five unique strata have been distinguished by predominant land use, habitat, and landmarks (Figure 1; Table 1) and are referenced throughout this report.

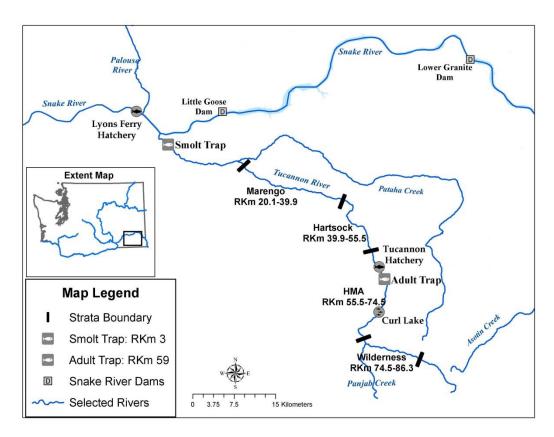

Figure 1. Location of the Tucannon River, and Lyons Ferry and Tucannon Hatcheries within the Snake River basin.

Table 1. Description of five strata within the Tucannon River.

			River
Strata	Land Ownership/Usage	Spring Chinook Habitata	Kilometerb
Lower	Private/Agriculture & Ranching	Not-Usable (temperature limited)	0.0-20.1
Marengo	Private/Agriculture & Ranching	Marginal (temperature limited)	20.1-39.9
Hartsock	Private/Agriculture & Ranching	Fair to Good	39.9-55.5
HMA	State & Federal/Recreational	Good to Excellent	55.5-74.5
Wilderness	Federal/Recreational	Excellent	74.5-86.3

^a Strata were based on water temperature, habitat, and landowner use.

b Rkm descriptions: 0.0-mouth at the Snake River; 20.1-Territorial Rd.; 39.9-Marengo Br.; 55.5-HMA Boundary Fence; 74.5-Panjab Br.; 86.3-Rucherts Camp.

Adult Salmon Evaluation

Broodstock Trapping

The allowed collection goal for broodstock is 170 adult salmon, depending upon size and fecundity, collected from throughout the duration of the run to meet the smolt production/release goal of 225,000. The proportion of natural origin fish incorporated into the broodstock is based on the estimated run size and the Tucannon Spring Chinook Salmon HGMP sliding scale. Additional jack salmon may be collected up to their proportion of the run with an upper limit of 10% used in broodstock, if needed. Returning Tucannon hatchery salmon were identified by coded-wire tag (CWT) in the snout, with no adipose fin clips. All adipose clipped fish captured at the trap are killed outright as strays.

The TFH adult trap began operation in February (for steelhead) with the first spring Chinook captured on 24 May (Appendix B). State and Tribal Fisheries Managers decided to collect all Tucannon River returns that would not be used for broodstock and hold them at LFH for outplanting back into the river closer to the commencement of spawning (See Adult Outplanting Section). These measures were taken to reduce potential in-river pre-spawn mortality that has been observed in preceding years. Adipose clipped strays (38 adults and jacks) were killed outright at the trap and all unclipped jacks were transported to LFH for holding for potential fisheries management options (outplanting, broodstock supplementation, or killed outright). The trap was operated through 30 September. A total of 431 fish entered the trap (62 natural adults, 11 natural jacks, 297 hatchery adults, and 61 hatchery jacks), and 37 natural (37 adults, 0 jacks) and 123 hatchery (123 adults, 0 jacks) spring Chinook were collected and hauled to LFH for broodstock (Table 2, Appendix B). A total of 215 fish (14 natural adults, 7 natural jacks, 135 hatchery adults, 59 hatchery jacks) were given a right opercle punch and were held at LFH for adult outplanting (Table 2, Appendix B). Adults collected for broodstock were injected with tulathromycin (Draxxin³) at 2.5 mg/kg, but fish held for adult outplants were not injected per WDFW Fish Health regulations. Antibiotic injections for broodstock were repeated 30 days prior to spawning. Broodstock and fish held at LFH received formalin drip treatments during holding at 167 ppm every other day at LFH to control fungus.

Tucannon River Spring Chinook Salmon Hatchery Evaluation Program 2018 Annual Report

³ The use of trade names does not imply endorsement by the Washington Department of Fish and Wildlife.

^a Fish identified as strays at the adult trap are killed outright. Some hatchery jacks were killed outright in 2016.

^b Two males (one natural, one hatchery) captured were transported back downstream to spawn in the river.

^c Three hatchery males that were captured were transported back downstream to spawn in the river.

^d Ninety-four natural origin fish were collected for broodstock; however, eight natural origin females were returned to the river for natural spawning leaving a total of 86 natural origin fish collected for broodstock.

^e None of the fish held for adult outplanting in 2017 were outplanted. All of the fish held for adult outplanting were < 61 cm in fork length (jack size) and were either used to supplement broodstock (natural jacks) or were killed outright.

Broodstock Mortality

Twenty (12.5%) of the 160 salmon collected for broodstock died prior to spawning in 2018 (Table 3). This rate was higher than recent years, even after the re-initiation of antibiotic injections in 2018 after the practice was stopped for the 2017 BY, and may have been due to handling. However, even higher mortality was experienced when fish were held at TFH (1986-1991), likely due to higher water temperatures (Table 3). Two of the pre-spawn mortalities during 2018 were stray Umatilla River hatchery males (CWT 090918).

Table 3. Numbers of pre-spawning mortalities and percent of fish collected for broodstock at TFH and held at TFH (1985-1991) or LFH (1992-2018).

Broodstock Spawning

Spawning at LFH was conducted once a week from 28 August to 18 September, with peak eggtake occurring on 11 September. During the spawning process, the eggs of two females were split in half and fertilized by two males following a 2 x 2 factorial spawning matrix approach. Factorial mating can have substantial advantages in increasing the genetically effective number of breeders (Busack and Knudsen 2007). The priority order of crosses was Natural x Hatchery, Natural x Natural, and Hatchery x Hatchery, depending upon availability and origin of ripe fish on a weekly basis.

A total of 212,973 eggs were collected from 76 spawned females (Table 4). Eggs were initially disinfected and water hardened for one hour in an iodophor (buffered iodine) solution (100 ppm). The eggs were incubated in vertical tray incubators. Fungus on the incubating eggs was controlled with formalin applied every-other day at 1,667 ppm for 15 minutes. Mortality to eye-up was 3.1%, which left 206,334 live eggs. An additional 0.95% (1,970) loss of eggs and sac-fry left 204,364 fish for production.

Table 4. Number of fish spawned or killed outright (K.O.), estimated egg collection, and egg mortality of natural and hatchery origin Tucannon River spring Chinook salmon at LFH in 2018. (Numbers in parentheses were live spawned).

Broodstock BKD Screening and Virology Testing

Broodstock females were screened for Bacterial Kidney Disease (BKD), caused by the bacterium *Renibacterium salmoninarum*, using Enzyme Linked Immunosorbent Assay (ELISA). Only 4% of the spawned females had high values in 2018 (Table 5). This is considerably lower than values from 2017, which were believed to be directly related to the decision to suspend antibiotic injections during that year (Figure 2). Eggs and progeny from high BKD ELISA broodstock were segregated from those of below low BKD ELISA broodstock.

Spawned females were also examined for viruses and sampling showed no evidence of virus in the samples tested.

Adult Outplanting

After discussions with the Tribal co-managers, it was decided to collect all returning fish not collected for broodstock or killed outright (hatchery strays) and hold them at LFH for adult outplanting back into the river during late August near the on-set of spawning. This joint decision was made due to the relatively low run size and the high pre-spawn mortality rate of adult spring Chinook salmon that has been documented in the Tucannon River in recent years (Gallinat and Ross 2014; Gallinat and Ross 2015; Snake River Lab 2015).

A total of 215 fish (21 natural origin, 194 hatchery origin) were collected for adult outplanting at the adult trap and given a right opercle punch. Held fish were treated with formalin to control fungus growth, but were not injected with antibiotics. Of the fish that were held, 12 hatchery origin fish died at LFH (5.6% pre-spawn mortalities). The remaining 203 fish were transported back to the river in small groups (~15 pairs/group) and released above Curl Lake (rkm 65.6) at six different locations on 16 August and 17 August (Table 6). Fish captured in the adult trap after 17 August were given a left opercle punch (LOP) and passed upstream. Stream surveys were conducted prior to and following adult outplanting and no pre-spawn mortalities of outplanted fish were recovered.

The furthest downstream an outplanted fish was recovered was rkm 64.8, suggesting that movement of outplanted fish from the release sites was negligible. Some redd superimposition was observed in the upper watershed.

Natural Spawning

Pre-spawn mortality surveys were conducted from 15 June to 20 August during 2018, after which regular weekly spawning ground surveys commenced. Although fish were not passed above the trap prior to 17 August, pre-spawn mortality surveys were still conducted upstream of the trap in case fish were able to bypass the trap. The pre-spawn mortality surveys covered from Panjab Bridge (rkm 74.5) to Bridge 10 (rkm 43.3) and totaled 88 river kilometers. Only two unidentifiable backbones were found, and those were recovered below the adult trap (one on 3 July at rkm 58.2 and one on 13 July at rkm 57.4). Cause of death could not be determined for either of the two pre-spawn mortalities.

Weekly spawning ground surveys were conducted from 21 August to 1 October 2018 and a total of 231 river kilometers were surveyed. One hundred-nine redds were counted and 9 natural and 58 hatchery origin carcasses were recovered (Table 7). Seventy-seven redds (71% of total) and 51 carcasses (76% of total) were found above the adult trap. All of the 16 carcasses recovered below the trap were hatchery strays (two CWT 090910, two CWT 090918, and 12 AD/No wire).

Table 7. Numbers and general locations of salmon redds and carcasses (includes pre-spawn mortalities) recovered on the Tucannon River spawning grounds, 2018 (the Tucannon Hatchery adult trap is located at rkm 59).

Historical Trends in Natural Spawning

Two general spawning trends were evident (Figure 3) from the program's inception in 1985 through 1999:

- 1) The proportion of the total number of redds occurring below the adult trap increased; and
- 2) The density of redds (redds/km) decreased in the Tucannon River.

In part, these two factors were a result of a greater emphasis on broodstock collection in an effort to reduce the risk of extinction. Moving the release location from TFH (rkm 57.7) upstream to Curl Lake AP (rkm 65.6) in 1999 appears to have affected the spawning distribution, with higher numbers of fish and redds in the Wilderness and HMA strata compared to previous years (Table 8). The number of redds above the trap has increased from the mid to late 90s, even during recent years with low numbers of adult returns, due in large part to adult outplanting in the upper watershed.

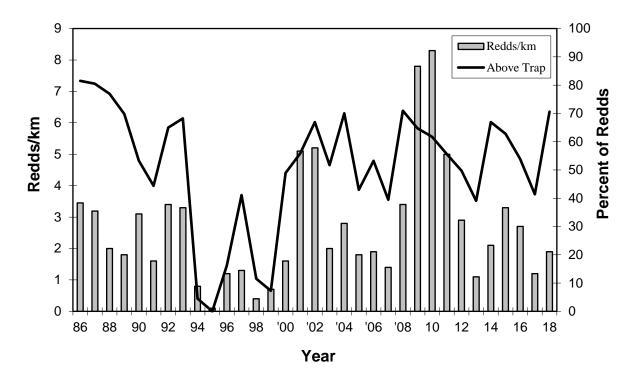

Figure 3. Number of redds/km and percentage of redds above the adult trap on the Tucannon River, 1986-2018.

Table 8. Number of spring Chinook salmon redds and redds/km (in parenthesis) by stratum and year, and the number and percent of redds above and below the TFH adult trap in the Tucannon River, 1985-2018.

Note: – indicates the river was not surveyed in that section during that year.

^a Excludes redds found below the Marengo stratum.

^b Includes all redds counted during redd surveys.

^c The 1985 redd counts were revised to account for all redds during the spawning season (WDFW 2017).

Stream Nutrient Enrichment

The majority of hatchery broodstock carcasses have traditionally been buried on-site at LFH after spawning. However, declines in salmonid abundance during the last century have resulted in decreased deposition of marine-derived nutrients and pose a significant restraint in the recovery of threatened and endangered Pacific salmon (Nehlsen et al. 1991; Scheuerell et al. 2005). The importance of marine derived nutrients to salmon recovery efforts has prompted local volunteer groups and state, federal, and tribal agencies to add supplemental nutrients into freshwater habitats, especially in salmon depleted habitats (Kohler et al. 2012). Stream nutrient enrichment efforts in the Tucannon River had been sporadic during the history of the hatchery program. However, since 2016, stream nutrient enrichment has been occurring on an annual basis.

A total of 1,305 Chinook salmon carcasses (primarily fall Chinook) were available for stream nutrient enrichment in the Tucannon River as the result of hatchery spawning at LFH during 2018. Virology testing did not show presence of pathogens, so the WDFW's "Protocols for the Nutrient Enrichment of the Tucannon River to Increase Production of Salmon and Steelhead" were followed and the fall Chinook carcasses, due to their relative abundance, were used as a surrogate for spring Chinook carcasses. Department employees and volunteers from the Tri-State Steelheaders Regional Fisheries Enhancement Group and AmeriCorps volunteers distributed the carcasses between Panjab Bridge (rkm 74.5) and near Highway 12 Bridge (rkm 22.0) from 5 October 2018 and 11-12 January 2019 (Table 9). Carcasses were distributed to benefit both spring Chinook and steelhead based on redd locations and expected downstream movement of juveniles and stream drift of aquatic macroinvertebrates.

Standard tracking of salmon/steelhead production and growth will occur and characteristics of juveniles (numbers, size, weight, condition factor, etc.) captured at the Tucannon River smolt trap will be monitored.

Table 9. Summary of Chinook salmon carcass distribution on the Tucannon River on 5 October 2018 and 11-12 January 2019.

Genetic Sampling

During 2018, we collected 192 DNA samples (tissue samples) from hatchery broodstock and carcasses collected from the spawning grounds (42 natural origin, 134 hatchery supplementation, and 16 hatchery origin strays). These samples were sent to the WDFW genetics lab in Olympia, Washington for storage. Genetic samples from the broodstock were also collected and sent to the Idaho Department of Fish and Game for parentage-based tagging analysis. Genotypes, allele frequencies, and tissue samples from previous sampling years are available from WDFW's Genetics Laboratory.

Age Composition, Length Comparisons, and Fecundity

We determine the age composition of each year's returning adults from scale samples of natural origin fish, and both scales and CWTs from hatchery-origin fish collected for broodstock and

from carcasses collected during spawning ground surveys. This enables us to compare ages of natural and hatchery-reared fish, and to examine trends and variability in age structure. The recovery of jack salmon from the river is low and jacks are typically not collected for broodstock so their representation is biased low compared to observations from the adult trap.

Overall, hatchery origin fish return at a younger age than natural origin fish and have fewer age-5 fish in the population (Figure 4). This difference is likely due to larger size-at-release that can lead to higher proportions of early maturating fish (hatchery origin smolts are generally 40-50 mm greater in length than natural smolts). The age composition for both hatchery and natural origin fish that returned in 2018 had fewer age-3 and 5 fish compared to the historical age composition (Figure 4). This is likely the result of poor ocean conditions during the past few years. We have not seen significant change in the mean age (weighted) of males and females over 28 brood years (Figure 5). The age composition by brood year for natural and hatchery origin fish is found in Appendix C.

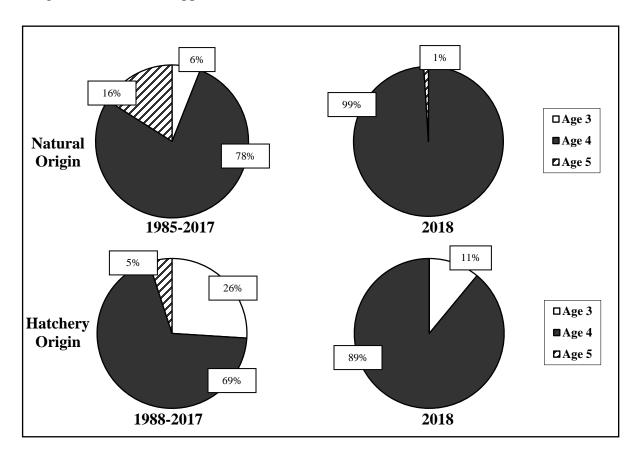

Figure 4. Historical (1985-2017), and 2018 age composition (run year) for spring Chinook in the Tucannon River.

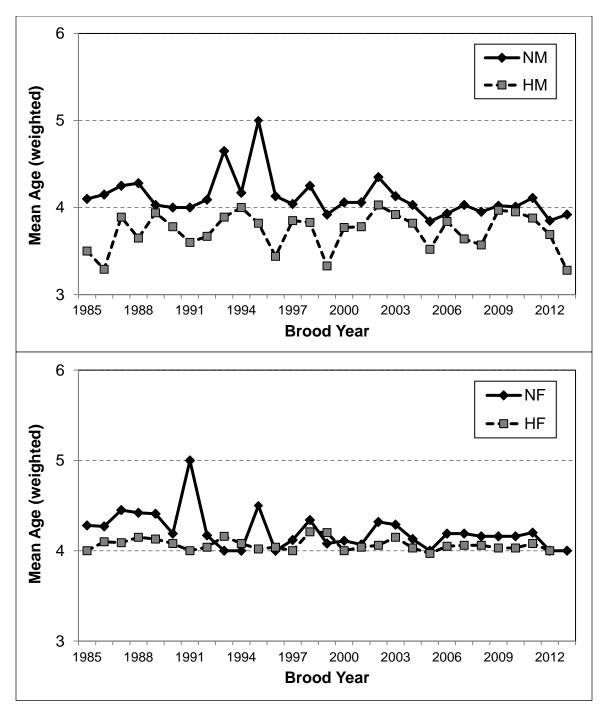

Figure 5. Weighted mean age of natural and hatchery origin males (NM, HM) and natural and hatchery origin females (NF, HF) for the 1985 to 2013 brood years for spring Chinook in the Tucannon River.

Another metric monitored on returning adult natural and hatchery origin fish is size at age, measured as the mean post-orbital to hypural-plate (POH) length. We examined size at age for age-4 adult returns using multiple comparison analysis from 1985-2018 and found a significant difference (P < 0.001) in mean POH length between age-4 natural and hatchery-origin female, and age-4 natural and hatchery-origin male spring Chinook salmon (Figure 6).

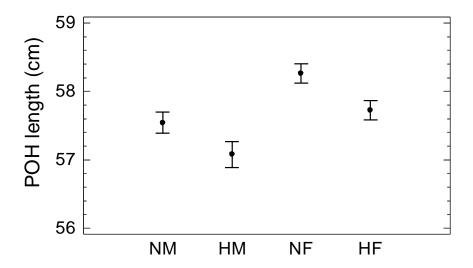

Figure 6. Mean post-orbital to hypural-plate (POH) length comparisons between age-4 natural and hatchery-origin males (NM and HM) and natural and hatchery-origin females (NF and HF) with 95% confidence intervals for the years 1985-2018.

To estimate fecundities (number of eggs/female) from the 2018 return year, dead eggs were counted for each female and a subsample of 100 live eyed-eggs was weighed. The total mass of live eggs was also weighed, and divided by the average weight per egg to yield total number of live eggs. This estimate was decreased by 4% to compensate for adherence of water on the eggs (WDFW Snake River Lab, unpublished data). Fecundities of natural and hatchery origin fish from the Tucannon River program have been documented since 1990 (Table 10). We performed an analysis of variance to determine if there were differences in mean fecundities of hatchery and natural origin fish. The significance level for all statistical tests was 0.05. Natural origin females were significantly more fecund than hatchery origin fish for both age-4 (P < 0.001) and age-5 fish (P < 0.001).

These data correspond with data collected by Gallinat and Chang (2013) that examined the effects of hatchery rearing on selected phenotypic traits of female Tucannon River spring Chinook salmon. They found that hatchery origin females had significantly lower fecundity than natural origin fish after correcting for body size. They also observed that the progeny of captive-reared broodstock, released as smolts and recaptured as returning age-4 adults, had a size and

fecundity distribution that was similar to the hatchery-origin adults, suggesting that the decrease in fecundity was related to hatchery rearing and not a genetically linked trait.

Table 10. Average number of eggs/female (n, SD) by age group of Tucannon River natural and hatchery origin broodstock, 1990-2018 (partial spawned females are excluded).

Arrival and Spawn Timing Trends

We monitor peak arrival and spawn timing to determine whether the hatchery program has caused a shift (Table 11). Peak arrival dates were based on the greatest number of fish trapped on a single day. Peak spawn in the hatchery was determined by the day when the most females were spawned. Peak spawning in the river was determined by the highest weekly redd count.

Peak arrival to the TFH adult trap was slightly later than normal for hatchery origin fish during 2018, but was within the historical range (Table 11). Peak spawning date in the hatchery was 11 September for both hatchery and natural origin fish, and was close to the historical mean (Table 11). The duration of spawning in the hatchery (22 days) was also close to the historical mean. Spawning in the river peaked on 12 September. The duration of active spawning in the Tucannon River (42 days) was within the range found from previous years.

Natural origin fish typically arrive earlier and at a slightly faster rate than hatchery origin fish (Figure 7). On average, about half of the total run of hatchery origin fish typically arrives at the adult trap by 12 June (Figure 7). After the end of June, the hatchery fish tend to arrive at the adult trap at a slightly faster rate than natural origin fish.

Table 11. Peak dates of arrival of natural and hatchery salmon to the TFH adult trap and peak (date) and duration (number of days) for spawning in the hatchery and river, 1986-2018.

^a Too few natural salmon were trapped in 1995 and 1999 to determine peak arrival.

^b Access restrictions during the Columbia Complex Forest Fire prohibited spawning ground surveys during the beginning of spawning.

^c Unspawned females determined to be in excess of eggtake goals were returned to the river for natural spawning which may have truncated duration of spawning in the hatchery.

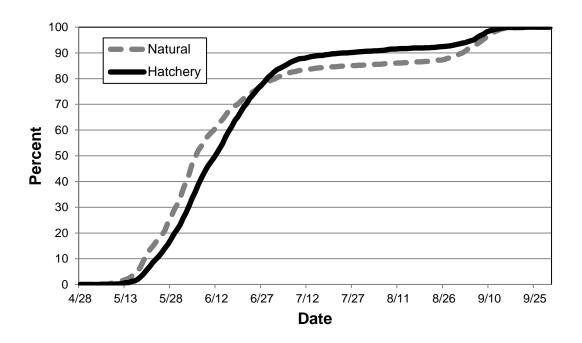

Figure 7. Cumulative run timing by date at the Tucannon Fish Hatchery adult trap on the Tucannon River for both natural and hatchery origin Tucannon River spring Chinook salmon, 1994-2018.

Total Run-Size

Redd counts have a strong direct relationship to total run-size entering the Tucannon River and passage of adult salmon at the TFH trap (Bugert et al. 1991). Numbers of fish passed upstream of the adult trap were adjusted to account for fish that were able to bypass the trap during the time it was in operation. We calculated separate bypass rates for both jacks and adults since their ability to bypass the trap has historically been different. Based on the presence or absence of left operculum punches from fish recovered during spawning ground surveys, we calculated the number of jacks and adults that bypassed the adult trap by solving for the following equation:

Number of fish⁴ that = $\underline{\text{Number of carcasses without operculum punches x Fish passed above trap}$ bypassed adult trap

Number of carcasses with operculum punches

Based on 2018 spawning ground carcass operculum punch recoveries, one jack and 48 adults were able to bypass the adult trap. We added the calculated number of fish that bypassed the trap (1 jack, 48 adults) to the number of fish that were passed upstream by hatchery staff (5 jacks, 13 adults), and adult outplants (65 jacks, 138 adults) for a total of 270 fish above the trap. The use of adult outplants confounded our typical calculation of the number of fish below the

Tucannon River Spring Chinook Salmon Hatchery Evaluation Program 2018 Annual Report

⁴ This formula was used to separately calculate for jacks and adults bypassing the adult trap. The word "fish" is used as a generic term referring to either adults or jacks.

adult trap since their survival was higher than fish that were passed upstream. The number of fish below the trap was calculated by the number of redds below the trap (32), multiplied by the fish/redd based on the sex ratio of the pre-spawning population that was collected at the adult trap (2.02). Therefore, the estimated number of fish below the trap was 65.

The run-size estimate for 2018 was calculated by adding the estimated number of fish upstream of the TFH adult trap (270), the estimated fish below the weir (65), adipose clipped strays killed at the trap (38), pre-spawn mortality of fish held for adult outplanting (12), and the number of broodstock collected (160) (Table 12). Run-size for 2018 was estimated to be 545 fish (80 natural adults, 0 natural jacks, and 425 hatchery adults, 40 hatchery-origin jacks). Historical breakdowns are provided in Appendix D.

^a In 1994, 1995, 1998 and 1999, fish were not passed upstream, and in 1996 and 1997, high pre-spawning mortality occurred in fish passed above the trap, therefore; fish/redd ratio was based on the sex ratio of broodstock collected.

b From 1985-1989 the TFH trap was temporary, thereby underestimating total fish passed upstream of the trap. The 1985-1989 fish/redd ratios were calculated from the 1990-1993 average, excluding 1991 because of a large jack run.

^c This total includes stray fish that are killed at the trap and pre-spawn mortalities of fish held at LFH for adult outplanting. During 2016, jacks were killed outright at the adult trap and are included in this total. During 2017, jacks were killed at LFH.

d Effort in looking for pre-spawn mortalities has varied from year to year with more effort expended during years with poor conditions or large runs.

^e The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2017).

f The fish/redd ratio was not used to estimate the number of fish below the adult trap due to survival differences between outplanted fish and fish that were passed upstream.

Spawning Escapement

To calculate spawning escapement, we assume one redd per female (Murdoch et al. 2009) and multiply the number of redds by the sex ratio (1.02 males: 1 female = 2.02 fish/redd) of the prespawning population that was collected at the adult trap (i.e., no carcass collection bias issues). This should provide a more accurate expansion method than simply applying a constant value based on assumptions, or data from other studies, since it incorporates the natural variability that occurs in most populations (Murdoch et al. 2010). Because spawner distribution of hatchery and natural origin fish may be different, we expanded the natural and hatchery fish by reach [Wilderness, HMA (above trap), HMA (below trap), Hartsock, Marengo, and below Marengo] based on carcass recoveries. The total for all reaches equals the spawning escapement.

Sex ratio from the adult trap was only available from 2000 to present. For 1985 to 1999, we used corrected carcass data based on the methodology of Murdoch et al. (2010). For years when the corrected carcass data produced clear outliers, or produced spawning escapements greater than the run escapement, we used data cited by Meekin (1967) that cited an average of 2.20 adults/redd and proportionately adjusted that figure up during years with high jack returns. The spawning escapement for 2018 was 220 fish (29 natural-origin, 191 hatchery-origin) based on 2.02 fish per redd. The estimated spawning escapement for 1985 to 2018 is found in Table 13.

^a The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2017).

Coded-Wire Tag Sampling

Broodstock collection, pre-spawn mortalities, and carcasses recovered during spawning ground surveys provide representatives of the annual run that can be sampled for CWT study groups (Table 14). In 2018, based on the estimated escapement of hatchery and natural origin fish to the river, we sampled approximately 51% of the run (Table 15).

Stray Salmon into the Tucannon River

Spring Chinook from other river systems (strays) are periodically recovered in the Tucannon River, although they were generally at a low proportion of the total run (Bumgarner et al. 2000). However, Umatilla River hatchery strays accounted for 8 and 12% of the total Tucannon River run in 1999 and 2000, respectively (Gallinat et al. 2001). Increased strays, particularly from the Umatilla River, was a concern since it exceeded the 5% stray proportion of hatchery fish deemed acceptable by NOAA Fisheries, and was contrary to fish management intent for the Tucannon River. In addition, the Oregon Department of Fish and Wildlife (ODFW) and the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) did not mark a portion of Umatilla River origin spring Chinook with an RV or LV fin clip (65-70% of releases), or CWT for the 1997-1999 brood years. Because of that action, some stray fish that returned from those brood years were physically indistinguishable from natural origin Tucannon River spring Chinook. Scale samples were collected from adults in those brood years to determine hatchery-origin fish based on scale pattern analysis. However, we are unable to differentiate between unmarked Tucannon fish and unmarked strays based on scale patterns. Beginning with the 2000 BY, Umatilla River hatchery-origin spring Chinook were 100% marked (adipose clipped), however, the implementation of a "stepping stone" hatchery management protocol for the Umatilla Hatchery Program has resulted in a portion of Umatilla Hatchery releases being unclipped (but 100% CWT) beginning with the 2009 BY. Unfortunately, because of that mark/tag, they are identical to Tucannon fish. As such, this hinders our ability to selectively remove stray hatchery fish during broodstock collection, or from fish passed upstream at the TFH adult trap. We will continue to monitor the Tucannon River and emphasize the need for external marks and CWTs for Umatilla River releases.

Fifty-seven strays (10 Umatilla River, 47 AD clip/no wire) were recovered during 2018 (Appendix E). Thirty-eight strays were killed outright at the trap (two CWT 090903, one CWT 090910 and 35 AD clip/no wire), 17 were recovered during spawning ground surveys (two CWT 090910, three CWT 090918, and 12 AD clip/no wire), and two were inadvertently collected for broodstock (CWT 090918). After expansions, strays accounted for an estimated 20.2% of the total 2018 run (Appendix E). This rate exceeds the 5% hatchery stray rate deemed acceptable by NOAA.

An added concern for the future is the implementation of a new hatchery program for the Touchet River using Carson stock spring Chinook. Potential straying from this hatchery program into the Tucannon River would be additive to the current stray rates being observed in the Tucannon River and could lead to outbreeding depression. All juveniles from the new Touchet River spring Chinook program will be 100% AD-clipped, with 34% of the production receiving CWT and 6% receiving PIT tags to monitor potential straying into the Tucannon River.

The increased use of passive integrated transponder (PIT) tags by fish and wildlife agencies and the utilization of in-stream PIT tag arrays in the Tucannon River have permitted us to identify the origin of some spring Chinook PIT tagged from other locations during 2018. Fourteen fish originally PIT tagged at locations other than the Tucannon River were detected in the Tucannon River (Table 16). The majority of these fish (13) were of unknown origin that were tagged as adults at Lower Granite Dam and eventually returned back downstream and entered the Tucannon River (Table 16). These fish could be Tucannon origin fish that overshot the river and returned back, however their actual origin is unknown. One stray (Cle Elum Hatchery, Easton Acclimation Pond, Yakama Nation) originally PIT tagged as a juvenile (2015 BY) was also detected in the Tucannon (Table 16).

Table 16. Tucannon River PIT tag array detections of spring Chinook originally tagged at locations other than the Tucannon River during 2018.

From the detected returns, 138 (24%) of the returning PIT tagged spring Chinook were detected upstream of the Tucannon River (Table 17; Appendix F). Forty-one of these fish (7%) had their last detections at or above Lower Granite Dam (Table 18; Appendix F). The overshoot rate has decreased over time and it is unknown whether this is related to changes in smolt release methods (from direct release to acclimation ponds with volitional release), changes in hydropower operations and river flows, changes in the proportion barged downstream, increases in tagging numbers/sample size, or greater detection capabilities in the Tucannon River (Table 18). This does not appear to be a hatchery effect as both natural and hatchery origin fish

overshoot the Tucannon River (Table 18). Non-direct homing behavior has been documented for adult Chinook in the Columbia River System (Keefer et al. 2008), and similar percentages of natural origin spring Chinook from the John Day River have been documented bypassing that river (Jim Ruzycki, ODFW, personal communication). However, more research into these events should be conducted to examine whether they are natural straying occurrences, or if it is related to hydropower operations. The installation of PIT tag arrays in the Tucannon River during the past few years [Lower Tucannon River (LTR) at rkm 2.2 - 2005, Middle Tucannon River (MTR) at rkm 17.8 and Upper Tucannon River (UTR) at rkm 44.4 - 2011, and Tucannon Fish Hatchery (TFH) at rkm 59.2 – 2012] have enabled us to document that the majority of the Tucannon spring Chinook that overshoot are able to make it back (about 70%) to the Tucannon River (Table 18). Returning spring Chinook overshooting the Tucannon River continues to be a concern, especially if they are unable to return to the Tucannon River, or if they return in a more compromised state (i.e., injuries from additional dam crossings), and may partially explain why this population has been slow to respond to recovery and supplementation actions.

Table 18. Number and origin of PIT tagged Tucannon River spring Chinook returns that overshoot the Tucannon River (includes fish that were last detected returning back downstream towards the Tucannon River) and also detected at Lower Granite Dam (LGR) that stayed above LGR Dam. Years with installed instream PIT tag arrays (2005 - 2017) are included for comparison.

Juvenile Salmon Evaluation

Hatchery Rearing, Marking, and Release

The 2017 BY were treated twice with Aquamycin-100[®] for two separate mortality events associated with BKD. They were treated initially as fry beginning shortly after diagnosis on 26 February 2018 and again on 18 June 2018. Supplementation juveniles (154,939) were tagged with CWT (63/73/96) at LFH from 26 June to 3 July 2018. Approximately 98,557 spring Chinook were transported to TFH from Lyons Ferry on 8 November 20178. An additional 54,786 fish were transferred on 4 December 2018. Fish were PIT tagged (target 15,000) for outmigration survival (Comparative Survival Study) and adult return estimates on 12 December 2018. The target release size was 38 g fish (12 fpp).

Brood year 2017 fish were sampled twice by WDFW evaluations staff during the rearing cycle (Table 19). During February, 1,895 fish were sampled for precocity (external observation only) and mark/tag quality and 280 were sampled for length and weight statistics. The 2017 BY fish were transferred to Curl Lake AP on 5 February 2019 for acclimation and volitional release. Length, weight, and precocity samples were repeated in April at Curl Lake AP prior to release (Table 19).

Table 19. Sample size (N), mean length (mm), coefficient of variation (CV), condition factor (K), mean weight (g), and precocity of 2017 BY juveniles sampled at TFH, and Curl Lake AP.

	Sample		Mean			Mean	%
Date	Location	N	Length (mm)	\mathbf{CV}	K	Wt. (g)	Precocity
2/04/19	TFH	280	125.1	13.1	1.26	25.7	1.16
4/02/19	Curl Lake	279	130.6	14.1	1.26	29.9	1.43

A large number of spring Chinook mortalities were observed at Curl Lake AP during volitional release. These mortalities may have been due to BKD. Mortalities were scanned for PIT tags and a total of 772 PIT tagged mortalities were counted. Since the number of fish that were originally PIT tagged (14,991) and the number of fish originally transferred to Curl Lake AP (152,049) were known, we used the proportion of PIT tagged fish to estimate the release number instead of using a 1% mortality rate as stated in the Annual Operation Plan. Volitional release began 4 April and continued until 3 May when the remaining fish were forced out. Estimated numbers and size of fish released are provided in Table 20. Historical release numbers are found in Appendix G.

Table 20. Preliminary spring Chinook salmon releases into the Tucannon River, 2019 release year.

Release	CWT	Total	Number	VIE	VIE Size	
Date	Code	Released	CWT	Mark	Total (kg)	Mean (g)
4/04-5/03	63/73/96	144,219	140,262	None	4,308	29.9

Smolt Trapping

Evaluation staff operated a 1.5 m rotary screw trap at rkm 3 on the Tucannon River from 16 October 2017 through 6 July 2018 to estimate numbers of migrating juvenile natural spring Chinook. Numbers of each fish species captured by month during the 2018 outmigration can be found in Appendix H. The main outmigration of natural origin spring Chinook for the 2017/2018 outmigration occurred during the spring, with a limited outmigration during the fall and winter months (Figure 8). Prior years have shown increased outmigration in the fall and winter from larger adult returns (Gallinat and Ross 2014, Gallinat and Ross 2015), although even in those years, the majority of the outmigration occurred in the spring.

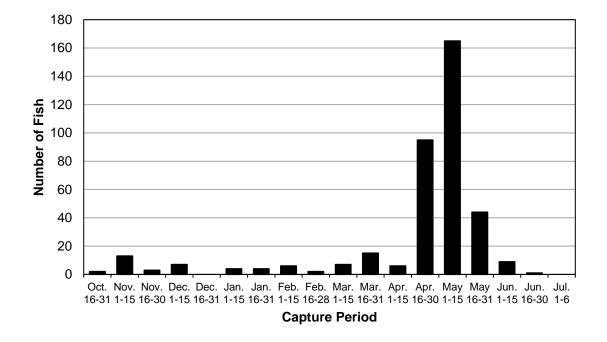

Figure 8. Emigration timing of natural spring Chinook salmon captured during smolt trap operations (rkm 3) on the Tucannon River for the 2017-18 migration year.

Natural spring Chinook emigrating from the Tucannon River (BY 2016) averaged 106 mm (Figure 9), with a CV of 8.6%. This is in comparison to a mean length of 162 mm for hatchery-origin fish (BY 2016) released from Curl Lake Acclimation Pond (Gallinat and Ross 2018).

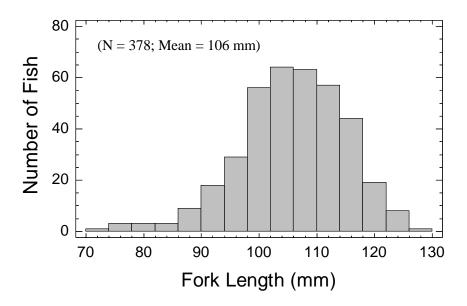

Figure 9. Length frequency distribution of sampled natural spring Chinook salmon captured in the Tucannon River smolt trap, 2017/2018 season.

Each week we attempted to determine trap efficiency by clipping a portion of the caudal fin on a representative subsample of captured migrants and releasing them approximately one kilometer upstream. The percent of marked fish recaptured was used as an estimate of weekly trapping efficiency. In previous reports we attempted to relate trap efficiency to abiotic factors such as stream flow or staff gauge level based on similar juvenile outmigration studies (Groot and Margolis 1991; Seiler et al. 1999; Cheng and Gallinat 2004). We found no significant relationships.

To estimate potential juvenile migrants passing when the trap was not operated for short intervals (≤ 5 days), such as periods when freshets washed out large amounts of debris from the river, we calculated the mean number of fish trapped for three days before and three days after non-trapping periods. The mean number of fish trapped daily was then divided by the estimated trap efficiency to calculate fish passage. The estimated number of fish passing each day was then applied to each day the trap was not operated.

We estimated outmigration based on the approach of Steinhorst et al. (2004). This involved using a Bailey-modified Lincoln-Peterson estimation with 95% bootstrap confidence intervals by running the Gauss Run-Time computer program (version 7.0). Bootstrap iterations numbered 1,000. The program allows for the division of the out-migration trapping season into strata with

similar capture efficiencies as long as at least seven marked recaptures occurred. Strata with less than seven recaptures were grouped with either the preceding or following strata, depending upon similarity in trapping/flow conditions. Where river conditions were similar, we used our best judgment to group the strata.

A number of assumptions are required to attain unbiased estimates of smolt production. How well the assumptions are met will determine the accuracy and precision of the estimates. Some of these assumptions are:

- Survival from release to the trap was 100%.
- All marked fish are identified and correctly enumerated.
- Fish do not lose their marks.
- All fish in the tag release group emigrate (i.e., do not residualize in the area of release).
- Marked fish are caught at the same rate as unmarked fish.

Accurate outmigration estimates are critical for describing survival trends and to measure population response to management actions such as hatchery supplementation and habitat restoration. It has been suggested that researchers test the assumptions of population estimators being used (Peterson et al. 2004; Rosenberger and Dunham 2005). Other WDFW researchers have identified bias in smolt trap efficiency estimates that were conducted similarly to Tucannon River trap efficiency tests. While the evidence of estimator bias and error seem consistent in the literature, our methods differ from those, and must be tested to estimate the level of error, and confirm compliance of the methods with underlying assumptions. If bias in our methods has been consistent over the term of the data, data could be adjusted as appropriate once bias is measured.

In past years, we attempted to measure bias in our efficiency estimates through the use of PIT tags and the PIT tag array that has been deployed in the lower Tucannon River below the smolt trap. Representative groups of fish were fin clipped and PIT tagged to determine smolt trap efficiency based on either recaptures in the smolt trap or detections by the PIT tag array in the Tucannon River. However, the PIT tag array proved unreliable in its detection of juvenile salmonids. If PIT tag technology in the future allows for greater detections of juvenile salmonids, then we will attempt to measure trapping bias again. We estimate that 8,058 (S.E. 2,730.5; 95% C.I. 4,618-16,014) migrant natural-origin spring Chinook (2016 BY) passed the smolt trap during 2017-2018.

Smolt Migration to Lower Monumental and McNary Dams

With the use of PIT tags, we monitored the migration travel time and speed of juvenile spring Chinook from the Tucannon River (both hatchery and natural origin) to Lower Monumental and McNary Dams for the 2018 outmigration. Hatchery fish were PIT tagged prior to transfer to Curl Lake AP (rkm 66) for acclimation, while natural origin fish were PIT tagged at the Tucannon River smolt trap (rkm 3), described earlier.

Hatchery fish were volitionally released from Curl Lake AP from 9 to 27 April 2018. The PIT tagging file submitted to PTAGIS allows for only one release date. Therefore, the following summary uses both 9 April and 27 April as the release date, since it is unknown when a PIT tagged fish actually left Curl Lake AP (Table 21). Based on previous observations, the majority of the spring Chinook do not exit the lake until towards the end of the release period.

Natural origin spring Chinook were released immediately following PIT tagging at the smolt trap, so the release date/time provided in the PTAGIS tagging files have been used for travel time/speed calculations. Natural origin fish detected at Lower Monumental and McNary dams in 2018 were PIT tagged at the smolt trap and released between 14 February to 28 May 2018 (Table 21). Natural-origin fish tend to have faster migration time to the dams than hatchery-origin fish (Table 21).

Table 21. Median and mean travel time and outmigration speed of hatchery and natural-origin Tucannon River spring Chinook to Lower Monumental and McNary Dams in 2018.

Survival Rates

Point estimates of population sizes have been calculated for various life stages (Tables 22 and 23) of natural and hatchery-origin spring Chinook from spawning ground and juvenile mid-summer population surveys, smolt trapping, and fecundity estimates. Survivals between life stages have been calculated for both natural and hatchery salmon to assist in the evaluation of the hatchery program. These survival estimates provide insight as to where efforts should be directed to improve not only the survival of fish produced within the hatchery, but fish in the river as well.

As expected, juvenile (egg-parr-smolt) survival rates for hatchery fish are considerably higher than for naturally reared salmon (Table 24) because they have been protected in the hatchery. However, SARs to the Tucannon River of natural salmon were almost eight times higher (based on geometric means) than for hatchery-reared salmon (Tables 25 and 26). With the exception of the 2006 brood year, hatchery SARs (mean 0.24%; geometric mean 0.17%) documented from the 1985-2013 broods have been well below the original LSRCP survival assumption of 0.87% (which was used to size the original hatchery program of 132,000 smolts). Hatchery SARs for Tucannon River salmon need to substantially improve to meet the mitigation goal of 1,152 hatchery adult salmon. The target size at release was increased to 38 g fish (12 fpp) beginning with the 2011 brood year in an attempt to improve poor smolt-to-adult return survival rates.

Table 22. Estimates of *natural in-river produced* Tucannon spring Chinook salmon (both hatchery and natural origin parents) abundance by life stage for 1985-2018 broods.

^a 1985 and 1989 mean fecundity of natural females is the average of 1986-88 and 1990-93 brood years.

^b Number of parr estimated from electrofishing (1985-1989), Line transect snorkel surveys (1990-1992), and Total Count snorkel surveys (1993-2005).

^c Numbers do not include down river harvest or other out-of-basin recoveries.

^d The 1985 redd counts were revised on the SASI database to account for all redds during the spawning season (WDFW 2017)

^e Smolt estimates could not be estimated with the GAUSS program for the 1991 and 1995 brood years. Numbers of smolts for those brood years were obtained from estimates in the annual reports.

Table 23. Estimates of Tucannon spring Chinook salmon abundance (*spawned and reared in the hatchery*) by life stage for 1985-2018 broods.

^a 1985 and 1989 mean fecundity of natural females is the average of 1986-88 and 1990-93 brood years; 1999 mean fecundity of natural fish is based on the mean of 1986-1998 brood years.

b Numbers do not include down river harvest or other out-of-basin recoveries.

^c Number of smolts is less than actual release number. 57,316 parr were released in October 1993, with an estimated 7% survival. Total number of hatchery fish released from the 1992 brood year was 140,725. We therefore use the listed number of 87,752 as the number of smolts released.

Parr determined to be in excess of program goals were released at Russell Springs and are not included in number of parr and smolts.

Table 24. Percent survival by brood year for juvenile salmon and the multiplicative advantage of hatchery-reared salmon over naturally-reared salmon in the Tucannon River.

Expanded numbers are calculated from the proportion of each known age salmon recovered in the river and from broodstock collections in relation to the total estimated return to the Tucannon River. Expansions do not include down river harvest or Tucannon River fish straying to other systems.

b One known (expanded to two) Age 6 salmon was recovered.

^c Numbers of smolts obtained from estimates in the annual reports.

d The 2014 and 2015 SARs are not included in the mean.

Expanded numbers are calculated from the proportion of each known age salmon recovered in the river and from broodstock collections in relation to the total estimated return to the Tucannon River. Expansions do not include down river harvest or Tucannon River fish straying to other systems.

As previously stated, overall survival of hatchery salmon to return as adults was higher than for naturally reared fish because of the early-life survival advantage (Table 24). With the exception of eleven brood years (37%), naturally produced fish have been below the replacement level (Figure 10; Table 27). Based on adult returns from the 1985-2014 broods, naturally reared

b The 2014 and 2015 SARs are not included in the mean.

salmon produced only 0.72 adults for every spawner, while hatchery reared fish produced 2.08 adults (based on geometric means).

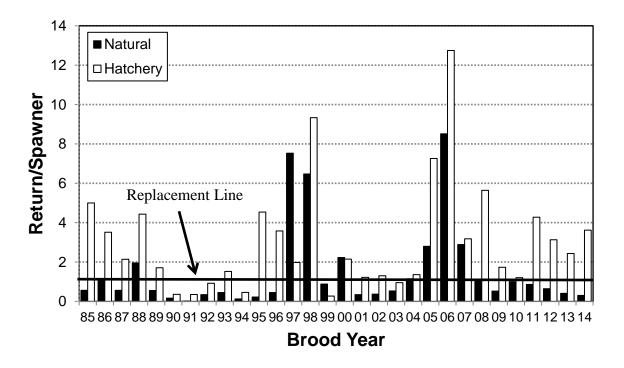

Figure 10. Return per spawner (with replacement line) for the 1985-2014 brood years (2014 incomplete brood year).

Table 27. Progeny-to-parent survival estimates of Tucannon River spring Chinook salmon from 1985 through 2014 brood years (2014 brood year incomplete).

Beginning with the 2006 brood year, the annual smolt goal was increased from 132,000 to 225,000 to help offset for the higher mortality of hatchery-origin fish after they leave the hatchery. This should increase adult salmon returns back to the Tucannon River. However,

based on current hatchery SARs the increase in production would still not produce enough adult returns to reach the LSRCP mitigation goal. Hatchery production changes that result in increased survival/return numbers may result in a Proportionate Natural Influence (PNI) of less than 0.5. This level is generally not considered acceptable for supplementation programs. Historically the PNI for the Tucannon Spring Chinook Program has generally been above 0.5 (Appendix I).

The long-term restoration goal for the State of Washington is to provide a total annual return of between 2,400-3,400 hatchery and natural origin spring Chinook salmon back to the Tucannon River (SRSRB 2006) that should include at least 750 natural origin fish over a 10-year geometric mean (population viability threshold) (ICTRT 2008). Natural origin returns had been increasing, but decreased during recent years (2016-2018) due to poor ocean conditions (Figure 11).

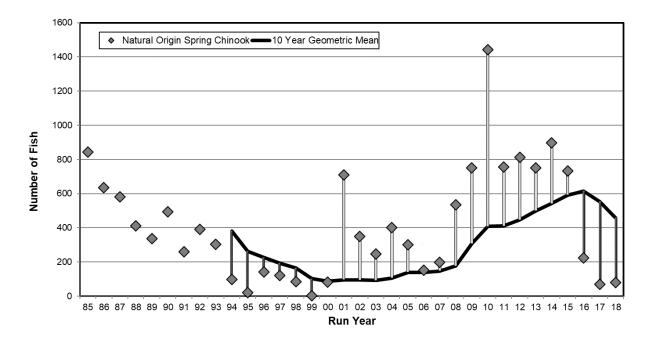

Figure 11. Tucannon River spring Chinook natural origin returns with the moving ten-year geometric mean (black line) for the 1985-2018 run years.

Fishery Contribution and Out-of-Basin Straying

The original goal of the LSRCP supplementation program was to enhance returns of salmon to the Tucannon River by providing 1,152 adult hatchery origin fish (the number estimated to have been lost to the project area due to the construction and operation of the Lower Snake River hydropower system) to the river from hatchery-reared smolt releases. Such an increase would allow for limited harvest and increased spawning. However, hatchery adult returns have always been below the mitigation goal (Figure 12). Based on CWT recoveries reported to the Regional Mark Information System (RMIS) database (Appendix J), sport, commercial, and treaty ceremonial harvest combined accounted for an average of less than 6% of the adult hatchery fish recovered for the 1985-1996 brood years. Increased fishery impacts occurred for the 1997 through 1999 broods when the states implemented mark-selective fisheries in the lower Columbia River (fishery harvest comprised an average of 19% for hatchery fish recoveries). As such, the WDFW subsequently stopped adipose fin clipping spring Chinook hatchery production from the Tucannon River (Gallinat et al. 2001) to lessen non-tribal fishery impacts from the Columbia River, and newly implemented Snake River fisheries. This change in marking has resulted in lower sport fishery impacts. Based on CWT recoveries for the 2000-2015 brood years, harvest (primarily commercial) has accounted for only 5.8% of the hatchery adult CWT recoveries (Appendix J).

Out-of-basin stray rates of Tucannon River spring Chinook have generally been low (Appendix J), with an average of 3.3% of the adult hatchery fish straying to other river systems/hatcheries for brood years 1985-2015 (range 0-100%). Recent (2005-2015 BYs) locations that Tucannon River spring Chinook have strayed are listed in Table 28.

Adjusted Hatchery SAS

Using CWT recoveries from the RMIS database, we adjusted Tucannon River spring Chinook hatchery smolt-to-adult survival (SAS) to include all known recoveries both from within and outside the Tucannon River. Increased fishing mortality resulted in higher adjusted SAS for the 1997, 1998, and 2006 brood years. With minor exceptions (1997 and 2006 brood years), even after adjustment, hatchery SAS were still below the original LSRCP survival assumption of 0.87% (Table 29).

Table 29. Hatchery SAS adjusted for recoveries from outside the Tucannon River subbasin as reported in the RMIS database, 1985-2013 brood years. (Data downloaded from RMIS database on 2/13/19).

^a Includes expanded RMIS CWT recoveries from sources outside the Tucannon River Subbasin (i.e., sport and commercial fisheries, Tucannon strays in other river systems, etc.).

LFH vs. TFH Reared Comparison

As mentioned earlier in this report, Tucannon River spring Chinook salmon that are collected for broodstock at the TFH adult trap are transported to LFH for holding and spawning, and incubation and early life rearing. This is primarily due to the availability of colder, pathogen free water and rearing space at LFH. However, during the review of the Tucannon River Spring Chinook HGMP, the Hatchery Scientific Review Group recommended developing long-term rearing capabilities within the Tucannon River Subbasin as one of their recommendations for the hatchery program (HSRG 2009). This recommendation was based on questions that were raised as to whether rearing the hatchery fish for the majority of their early life at LFH affected their survival and ability to home back to the Tucannon River. To answer these questions, approximately 30,000 eggs were transferred to TFH for incubation and rearing for three brood years (BY11-13) for comparison to LFH reared fish (Appendix L). To avoid potential bias in recovery rates between the two release groups (Zhou 2002, Murdoch et al. 2010), we used PIT tag detections of migrating smolts and returning adults to compare performance and relative survival between the LFH reared and TFH reared groups of spring Chinook. Fish with PIT tags are detected through a network of interrogation systems currently in place in juvenile bypass systems and adult fishways at hydroelectric dams (Burke and Jepson 2006). In addition, small instream arrays have been developed to remotely detect PIT tagged fish (Zydlewski et al. 2006; Bond et al. 2007), and these units have been installed in the Tucannon River. Each group was tagged with a unique CWT and a subset (Target – 7,500) of each group was PIT tagged (Table 30).

Juvenile Survival

Survival probabilities were estimated by the Cormack-Jolly-Seber methodology using the Survival Under Proportional Hazards (SURPH) 3.0 computer model. The data files were created using the PitPro (version 4.19.7) computer program to translate raw PIT Tag Information System (PTAGIS) data of the Pacific States Marine Fisheries Commission into usable capture histories for the SURPH program. To determine significant differences in survival probabilities between groups, we used the Likelihood Ratio Test statistic. Estimated survival probabilities from Curl Lake to Lower Monumental Dam were not significantly different (P > 0.05) between the two groups (Table 30).

Adult Returns

Returning PIT tagged detected fish were assumed to be mature the year they entered freshwater after being in the marine environment. We calculated the smolt-to-adult survival (SAS) as the total number of fish that were detected within the Columbia and Snake River watersheds (Table

31). Smolt-to-adult return (SAR) was calculated as the number of fish that were detected in the Tucannon River (Table 31). We tested for differences in SAS and SAR rates between the two groups using a nonparametric Mann-Whitney (Wilcoxon) test, given that we were concerned about non-normality due to small sample sizes (Zar 1996). All statistical tests used a significance level of 0.05. Neither SAS (P = 0.82) nor SAR (P = 0.51) were significantly different between the two groups. The results do not show a significant benefit in either survival or homing back to the Tucannon River by rearing fish at TFH (Table 29). Based on these findings, we will continue to use LFH for holding and spawning, and incubation and early life rearing.

Table 30. Release number, size at release (g), and number of Tucannon River hatchery spring Chinook PIT tagged by brood year (BY) for each rearing location and SURPH survival probabilities from Curl Lake Acclimation Pond to Lower Monumental Dam for the 2011 to 2013 brood years.

Conclusions and Recommendations

Washington's LSRCP hatchery spring Chinook salmon program has failed to return adequate numbers of adults to meet the mitigation goal. This has occurred because SARs of hatchery origin fish have been consistently lower than what was originally assumed under the LSRCP program development. However, because of the advantage in survival during early life history stages for fish in the hatchery, the progeny-to-parent ratio for hatchery-produced fish has generally been above replacement and therefore may have sustained the overall Tucannon spring Chinook population during years when the population was at critically low levels. For a while, we had seen a significant rebound of natural origin fish and we came close to reaching the within river hatchery (LSRCP) goal of 1,152 fish in 2009 and 2010. Recent returns have been much lower, which is believed to be the result of recent poor ocean conditions. System survivals (in-river, migration corridor, and ocean) must increase in the near future for the hatchery program to succeed, the natural run to persist over the short-term, and the natural population to increase to a level where it can be sustainable over the long-term.

Until that time, the evaluation program will continue to document and study life history survivals, straying, carrying capacity, genotypic and phenotypic traits, and examine procedures within the hatchery that can be changed to improve the hatchery program and the natural population. Based on our previous studies and current data we recommend the following:

- 1. We continue to see annual differences in phenotypic characteristics of returning salmon (i.e., hatchery fish are generally younger and less fecund than natural origin fish), yet other traits such as run and spawn time are little changed over the program's history. Further, genetic analysis to date has detected little change in the natural population that may have resulted from hatchery actions.
 - <u>Recommendation</u>: Continue to collect as many carcasses as possible for the most accurate age composition data. Collect biological data (length, run timing, spawn timing, fecundity estimates, DNA samples, smolt trapping, and life stage survival) to document the effects (positive or negative) that the hatchery program may have on the natural population.
- 2. Based on annual redd densities and historical spring Chinook radio tag data, and PIT tag data from the TFH array, the Tucannon Fish Hatchery weir/trap has been an impediment to upstream passage of spring Chinook to the better spawning and rearing habitat upstream of the trap. Numerous options to improve attraction into the ladder/trap have been discussed with some recently implemented.

<u>Recommendation</u>: Monitor changes made to the ladder/trap to see if they improve passage for all fish species. If improvements are not seen, seek funding and engineering expertise to modify the design and/or operation of the weir/trap structure.

3. Subbasin and recovery planning for ESA listed species in the Tucannon River have identified factors limiting the spring Chinook population and strategies to recover the population.

<u>Recommendation</u>: Assist population conservation efforts by updating recent carrying capacity/density and straying effects, and productivity estimates of the Tucannon River so that hatchery stocking is appropriate, and hatchery and natural performance is measured against future basin capacity after habitat improvements.

4. We have documented that hatchery juvenile (egg-parr-smolt) survival rates are considerably higher than naturally reared salmon, and hatchery smolt-to-adult return rates are much lower than their natural origin counterpart. We need to identify and address the factors that limit hatchery SARs in order to meet mitigation goals and for natural production to meet recovery goals.

Beginning with the 2006 brood year, the annual hatchery smolt goal was increased from 132,000 to 225,000 to help offset the higher mortality of hatchery-origin fish after they leave the hatchery. In addition, the size of hatchery fish at release was increased in an attempt to increase hatchery survival. In theory, both of these actions should increase adult hatchery salmon returns back to the river, however, based on current survivals it does not appear these actions will produce enough adult returns to reach the LSRCP adult mitigation goal.

Because of this, WDFW, along with the co-managers, have proposed additional hatchery spring Chinook programs within SE Washington. A hatchery program using Tucannon River stock is in the planning stages for Asotin Creek, while a program using Carson stock has been approved for the Touchet River, with eyed eggs shipped to LFH from the 2018 brood year and first releases planned for the spring of 2020. Adult returns from these two additional hatchery programs will be additive to the Tucannon returns, and will contribute towards the LSRCP spring Chinook mitigation goal (1,152) for Washington.

Recommendation: Continue to compare hatchery and natural survival rates from other reference watersheds compare survival rates documented for Tucannon River spring Chinook. Continue to discuss alternative release strategies with the managers to see if survival rates can be improved to provide greater adult returns. Utilize fish carcasses from hatchery operations for stream nutrient enrichment to improve overall productivity and survival of Tucannon River spring Chinook. Continue to monitor straying into the Tucannon

River to insure the addition of Touchet River Carson stock hatchery fish does not go above the NOAA Fisheries acceptable stray proportion of 5%. Over the course of the next year, determine how the LSRCP mitigation goal will be partitioned between the Tucannon, Touchet, and Asotin Creek hatchery programs.

5. Over the last few years, we have documented higher in-river pre-spawn mortality than what was observed historically. The mechanism for this higher loss is thought to be due to a combination of drought years with higher water temperatures and pathogen load. However, the high loss has prompted drastic action within the program, whereby all, or the majority of the returns to the TFH trap between 2015 to 2018 have been collected and held at LFH for adult outplanting. Results from the first year (2015) of adult outplants appeared successful, with > 90% of the fish spawning, contrasted to 30% survival of fish left in the river. From 2016-2018, a range of 55-72% of outplanted fish successfully spawned.

Recommendation: Continue to monitor in-river pre-spawn mortality. Continue intensive monitoring of adult outplants, when that strategy is employed, to determine spawning success. Weigh all pertinent information (pre-spawn mortality rates, outplant success, predicted run sizes, risk of holding all fish at one facility, etc.) and inform co-managers and NOAA Fisheries on future adult outplants. An agreed upon population threshold trigger is needed to determine whether to pass fish at the adult trap or hold fish at LFH for outplanting. A trigger has been suggested by M&E staff (allow outplanting below an estimated return of 400 adults), but has yet to be agreed upon by the co-managers.

Appendix A: Annual Section 10 Permit #18024 Takes for 2018, and NEOR/SEWA Terms and Conditions Biological Opinion Reporting Requirements

Appendix A. Table 1. Summary of permissible direct take and actual take (in parenthesis) of Snake River spring/summer Chinook salmon for RM&E activities associated with the Tucannon River spring Chinook salmon program not directly related to fish culture for the 2018 calendar year. NMFS must be notified

within two days if the number handled, tagged, or killed are exceeded.

Origin and Life Stage	Take activity	Capture method And location	Total number handled annually (0.5% handling mortalities)	Number of those handled that are marked/tagged annually (1% handling mortalities	Total number killed or removed annually
Natural-origin juveniles	Capture, handle, tag, tissue sample, and release live animal.	Trapping operations that include a screw trap, beach seines, cast nets, dip nets, and use of backpack electroshock equipment throughout the Tucannon River.	18,000 (387)	7,000 (366)	Up to 160 (6)
Hatchery-origin juveniles	Capture, handle, tag, tissue sample, and release live animal.	Trapping operations that include a screw trap, beach seines, cast nets, dip nets, and use of backpack electroshock equipment throughout the Tucannon River.	35,000 (4,944)	7,000 (1,706)	Up to 245 (25)
Natural-origin adults & jacks	Capture, handle, tag, tissue sample, and release live animal.	Adult and jack fall back at screw traps.	5 (0)	5 (0) (genetic fin-clip or operculum punch – release live.)	Up to 2 ^a (0)
Hatchery-origin adults & jacks	Capture, handle, tag, tissue sample, and release live animal.	Adult and jack fall back at screw traps.	10 (0)	10 (0)	Up to 2 ^a (0)

^a In cases where total number killed is not likely to exceed one (1) mortality, NMFS rounds the total mortality up to two (2), so that operations are not halted completely at the first mortality.

Appendix A. Table 2. Summary of permissible direct take and actual take (in parenthesis) of listed Snake River spring/summer Chinook salmon for fish culture purposes for the Tucannon River Spring Chinook salmon program for the 2018 calendar year. NMFS must be notified within two days if the number

handled, tagged, or killed are exceeded.

Origin and Life Stage	Take activity	Capture method	Total number	Number of those handled that are marked/tagged annually (1% trap mortalities	Total number killed or removed annually
Natural-origin adults	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, remove for use for broodstock, or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	2,000 (62)	Up to 1,824b (passed live with finclip or operculum punch, PIT and/or radio tagged) (11 passed upstream) (14 outplanted upstream)	Up to 232 ^b broodstock and fish used for outplants (37 broodstock) Plus up to 19 adult trap mortalities (0)
Natural-origin jacks	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, remove for use for broodstock, or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	200 (11)	Up to 200 (passed live with fin- clip or operculum punch, PIT and/or radio tagged) (4 passed upstream) (7 outplanted upstream)	Up to 9 broodstock. (9) Plus up to 2 trap mortalities. (0)
Hatchery-origin adults	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, remove for use for broodstock, or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	1,400 ^b (up to 132 removed for broodstock based on sliding scale) (297)	Up to 1,400 ^b (passed live with finclip or operculum punch, PIT and/or radio tagged) (2 passed upstream) (124 outplanted upstream)	Up to 232 ^b broodstock and fish held for later outplanting. (123 broodstock) Up to 100% of total handled may be removed, killed, or transported as described in the HGMP (37 stray KO and 11 A.O. DIPs)
Hatchery-origin jacks	Capture, handle, tag, tissue sample, remove for transport, holding, and outplanting in the Tucannon River, use for broodstock, remove for adult management or release live animal (pass above weir).	Tucannon River adult weir and Lyons Ferry Hatchery ladder ^a	500 (61)	Up to 135 (more may be passed to mimic natural- origin jack proportions, with NMFS concurrence) (passed live with fin- clip or operculum punch) (1 passed upstream) (58 outplanted)	Up to 9 broodstock. (0) Up to 100% of remainder may be removed, transported, or killed for jack management as described in the HGMP (1 stray KO and 1 A.O. DIP)
Hatchery-origin egg & juveniles	Capture, handle, tag, tissue sample, and release live animal (within hatchery sampling, and research use).	Tucannon Hatchery or Lyons Ferry Hatchery total	280,125 (212,973 BY18) (Maximum eggs/juveniles on hand annually prior to any juvenile rearing loss)	280,125 154,939 BY17 CWT 14,956 BY16 PIT tagged	Up to 55,125 total rearing mortality (3,658 BY17) (9,352 BY18)
Hatchery-origin juveniles	Capture, sample, kill (fish health examinations)	Tucannon Hatchery or Lyons Ferry Hatchery total	170 (50)	170 (0)	170 (50)

^a In years when returns to Tucannon Hatchery are low, adult Chinook arriving at Lyons Ferry Hatchery ladder that are identifiable as Tucannon River hatchery adults may be taken for broodstock.

^b The actual number taken annually will be subject to the sliding scale in the HGMP, in addition to fish that are collected, held, and used for adult outplants in the Tucannon, but may die while holding, or be used as part of the broodstock, and shall not exceed the totals of each origin identified there.

^a PIT tag adult detection systems were in operation beginning in 1988 for LGR, 1998 for BON, 2002 for MCN, 2005 for both ICH and LTR, 2011 for MTR and UTR, and 2012 for TELL.

^b This fish was detected bypassing the Tucannon River (LGO or LGR detection) before heading back downstream.

Appendix F (continued). Final PIT tag detections of returning Tucannon River spring Chinook from fish originally tagged as juveniles from the Tucannon River.

^a PIT tag adult detection systems were in operation beginning in 1988 for LGR, 1998 for BON, 2002 for MCN, 2005 for both ICH and LTR, 2011 for MTR and UTR, and 2012 for TFH.

Appendix F (continued). Final PIT tag detections of returning Tucannon River spring Chinook from fish originally tagged as juveniles from the Tucannon River.

^a PIT tag adult detection systems were in operation beginning in 1988 for LGR, 1998 for BON, 2002 for MCN, 2005 for both ICH and LTR, 2011 for MTR and UTR, and 2013 for TEH.

^b This fish was detected bypassing the Tucannon River (LGO or LGR detection) before heading back downstream.

Appendix F (continued). Final PIT tag detections of returning Tucannon River spring Chinook from fish originally tagged as juveniles from the Tucannon River.

^a Release types are: Tucannon Hatchery Acclimation Pond (H-Acc); Portable Acclimation Pond (P-Acc); Curl Lake Acclimation Pond (C-Acc); and Direct Stream Release (Direct).

^b All tag codes start with agency code 63.

^c Codes listed in column are as follows: BWT - Blank Wire Tag; CB - Captive Brood; VI-Visual Implant (elastomer); LR - Left Red, RR - Right Red, LG-Left Green, RG - Right Green, LY - Left Yellow, RY - Right Yellow, LB - Left Blue, RB - Right Blue, LP - Left Purple; Oxytet. – Oxytetracycline Mark; Crosses: WxW - wild x wild progeny, HxH - hatchery x hatchery progeny, Mixed – wild x hatchery progeny.

^d No tag loss data due to presence of both CWT and BWT in fish.

e VI tag only.

f No wire.

Appendix H: Numbers of Fish Species Captured by Month in the Tucannon River Smolt Trap during the 2018 Outmigration

^a $\overline{PNI = PNOB/(PNOB + PHOS)}$.

PNOB = Percent natural origin fish in the hatchery broodstock.

PHOS = Percent hatchery origin fish among naturally spawning fish.

^a WDFW agency code prefix is 63.

b Fish trapped at TFH and held at LFH for spawning.
 c Data for the 2014 and 2015 brood years are incomplete.

Appendix K: Summary of egg distribution, egg loss, ponding numbers, and mean size for the LFH and TFH reared groups (2011-2013 brood years)

Appendix K. Summary of egg distribution, egg loss, ponding numbers, and mean size for the LFH and TFH reared groups (2011-2013 brood years) of Tucannon River spring Chinook.

	BY11	BY12	BY13
Number of eggs collected	325,701	269,514	275,188
Mortality to eye-up	14,551	15,262	8,357
Mortality to eye-up (%)	4.47	5.66	3.04
Live eggs left in trays	311,150	254,252	266,831
LFH:			
Live eggs reared at LFH	281,106	224,240	236,831
Additional egg loss	5,935	8,219	2,772
Additional egg loss (%)	2.11	3.67	1.17
Initial ponding numbers	275,171	216,021	234,059
TFH:			
Transfer from LFH to TFH	30,044	30,012	30,000
Additional egg loss	137	563	429
Additional egg loss (%)	0.46	1.88	1.43
Initial ponding numbers	29,907	29,449	29,571
January Sampling			
LFH – mean length (c.v.)	110.0 mm (12.3)	122.8 mm (13.0)	132.6 mm (17.3)
TFH – mean length (c.v.)	114.1 mm (11.7)	117.5 mm (8.5)	129.1 mm (17.8)
April Sampling – LFH & TFH			
Mean length (c.v.)	136.7 mm (17.9)	136.4 mm (15.2)	142.8 mm (15.4)

This program receives Federal financial assistance from the U.S. Fish and Wildlife Service Title VI of the Civil Rights Act of 1964, Section 504 of the Rehabilitation Act of 1973, Title II of the Americans with Disabilities Act of 1990, the Age Discrimination Act of 1975, and Title IX of the Education Amendments of 1972.
